## SUPPLEMENTARY REPORT

(This is a report giving the 1930 daily diversion records in acre-feet for those diversions for which the monthly data only is tabulated in Chapter III. This supplementary report is not published but is on file and available for reference in the office of the Division of Water Resources.)

## LIST OF TABLES

Table No.

1.	Discharge of Sacramento River at Kennett . . . . .	6
2.	Discharge of Sacramento River near Red Bluff . . . . .	7
3.	Discharge of Sacramento River at Butte City . . . . .	8
4.	Discharge of Sacramento River at Colusa . . . . .	9
5.	Discharge of Sacramento River at Knights Landing . . . . .	10
6.	Discharge of Sacramento River at Verona . . . . .	11
7.	Discharge of Sacramento River at Sacramento . . . . .	12
8.	Discharge of Butte Creek near East Side Highway . . . . .	13
9.	Discharge of Feather River at Nicolaus . . . . .	14
10.	Discharge of American River at Sacramento . . . . .	15
11.	Discharge of Mokelumne River at Woodbridge . . . . .	16
12.	Discharge of Mokelumne River at Thornton . . . . .	17
13.	Discharge of San Joaquin River near Vernalis . . . . .	18
14.	Summary of Sacramento River Diversions (Acre-feet) . . . . .	21
15.	Sacramento River Diversions . . . . .	22
16.	Colusa Trough Diversions . . . . .	43
17.	Back Borrow Pit Diversions . . . . .	44
18.	Lower Butte Creek and Butte Slough Diversions . . . . .	45
19.	By-Pass and Drainage Channel Diversions . . . . .	47
20.	Feather River Diversions . . . . .	51
21.	Yuba River Diversions . . . . .	54
22.	American River Diversions . . . . .	55
23.	Delta Uplands Diversions from Old San Joaquin River . . . . .	58
24.	Delta Uplands Diversions from Tom Paine Slough . . . . .	59

84. Salinity Stations at which Observations were taken During 1930 . . . . .	153
85. Salinity Observations, Sacramento-San Joaquin Delta and Upper Bays, 1930 . . . . .	156

LIST OF PLATES

<u>Plate No.</u>	
1. Accumulated Draft and Return Flow, Sacramento River, Red Bluff to Sacramento, June 1st to September 30, 1930 . . . . .	74
2. San Joaquin River Return Flow, June to September, Inclusive, 1930 . . . . .	92
3. Relation of Use of Water to Yield of Tops-Asparagus Tanks . . . . .	115
4. Relation of Use of Water to Yield of Spears-Asparagus Tanks. . . . .	121
5. Relation of Use of Water to Yield of Onions . . . . .	125
6. Relation of Use of Water to Yield of Barley . . . . .	129
7. Comparison of River Discharge and Salinity at Bay and Delta Stations, 1930 . . . . .	149

ACKNOWLEDGMENTS

It is desired to acknowledge and express appreciation for:

The hearty cooperation given by the various engineers, water superintendents, and water users throughout the territory covered by this work;

The cooperation of federal agencies including the Water Resources Branch of the U. S. Geological Survey, through H. D. Mc Glashan, District Engineer and the U. S. Department of Agriculture, Bureau of Agricultural Engineering, through W. W. McLaughlin, Associate Chief;

The untiring and efficient assistance of the engineers as listed under the organization statement who have been employed on this work during the past year.

ADVISORY COMMITTEE

## PERMANENT COMMITTEE OF THE SACRAMENTO-SAN JOAQUIN RIVER PROBLEMS CONFERENCE

The successful prosecution of the Water Supervisor's work both in stream administration and collection of records may be attributed in no small measure to the backing, advice, and continued interest and cooperation of the Permanent Committee of the Sacramento-San Joaquin River Problems Conference.

This Committee, representative of the water users and other interests involved, was appointed by the First Sacramento-San Joaquin River Problems Conference in January, 1924. Its present personnel is as follows:

Herbert E. White, Chairman, Sacramento	
E. L. Adams, Chico	Manly S. Harris, San Francisco
A. E. Anderson, San Francisco	W. I. Hechtman, Sherman Island
Alden Anderson, Sacramento	Warren H. McBryde, San Francisco
G. A. Atherton, Stockton	R. V. Meikle, Turlock
P. M. Downing, San Francisco	Jesse Poundstone, Grimes
William Durbrow, Grass Valley	F. T. Robson, Vina

ORGANIZATION

Walter E. Garrison - - - - - Director of Public Works

- - 0 - -

Harold Conkling - - - - - Deputy in charge of Water Rights

Harlowe M. Stafford  
Sacramento-San Joaquin Water Supervisor

Martin H. Blote - - - - - Assistant Water Supervisor  
James M. Brockway - - - - - Assistant Engineer  
Frederick E. Anderson - - - - - Assistant Engineer  
Ralph S. Rose - - - - - Assistant Engineer

DELTA COOPERATIVE INVESTIGATION

W. W. McLaughlin - - - - - Associate Chief,  
Bureau of Agricultural Engineering, U.S.Department of Agriculture.  
O. V. P. Stout - - - - - Hydraulic Engineer  
Lloyd N. Brown - - - - - Assistant Hydraulic Engineer

## CHAPTER I

## INTRODUCTION

Purpose

The purpose of this report is to make of record the measurements made and data collected through the office of the Sacramento-San Joaquin Water Supervisor during the 1930 irrigation season.

Origin and History of Work

This work was inaugurated in 1924 through the efforts of the first Sacramento-San Joaquin River Problems Conference and its Permanent Committee working with the former Division of Water Rights. The funds for the work in the first year were largely subscribed by the water users but subsequently it has been conducted under legislative appropriations included in the regular biennial budget of the Division. A complete description of the origin and history of this work will be found in the 1924 and 1926 Biennial Reports of the former Division of Water Rights, in Bulletin Number 4 of the same Division, and in Bulletin Number 23 of the Division of Water Resources. The latter bulletin brings together all data and measurements obtained by the Water Supervisor in the five year period, 1924 to 1928, inclusive. The reports for subsequent individual years are mimeographed as the present report, with the plan to again bring all data together in a printed bulletin at the end of the second five year period.

Scope

As outlined in previous reports this work is divided into (1) engineering investigations, measurements and collection of records, and

(2) conservation, waste prevention and such administration of the stream flow as shall fall within the jurisdiction of the Division of Water Resources or be mutually agreed upon by the water users. This report presents chiefly, for permanent record, the results of the engineering investigations. These comprise measurements and records of the diversions of water from the Sacramento, Feather, Yuba, American, Merced, Tuolumne, Stanislaus and San Joaquin rivers within the valley floor and above the Delta; stream flow measurements throughout the territory, largely in cooperation with the Water Resources Branch, U. S. Geological Survey; measurements and records of waters returned to the Sacramento and San Joaquin Rivers; studies of the consumptive use of water in the Sacramento-San Joaquin Delta in cooperation with the U. S. Department of Agriculture Bureau of Agricultural Engineering; an annual census of irrigated areas and crops under all diversions recorded and throughout the Delta; and observations and investigation of the advance and retreat of salinity in the Delta channels and Upper Bays.

#### Organization

The regular organization has included the Water Supervisor, Assistant Water Supervisor, and three assistant hydraulic engineers. The organization for the cooperative Delta investigations under the direction of W. W. McLaughlin, Associate Chief, Bureau of Agricultural Engineering, U. S. Department of Agriculture, has included an hydraulic engineer and one assistant giving full time to field work.

Under the direction of Martin H. Blote, Assistant Water Supervisor, engineers James M. Brockway and Ralph S. Rose have been responsible for the work above Sacramento, the former working from Meridian to Redding

and the latter from Sacramento to Meridian; Engineer Frederick E. Anderson has been responsible for the census of irrigated acreages and crops in the Delta, the work in the Delta uplands and that on the Feather, American, and Yuba Rivers; and engineers Brockway and Rose have carried out the return water and diversions measurements on the San Joaquin River and its tributaries. Major O. V. P. Stout has been in charge of the Delta Cooperative work with Engineer Lloyd N. Brown in resident charge at King Island.

### Conservation Features

A comparison of the run-off and water supply conditions in the 1930 season with those of the previous seasons in which the work of the Water Supervisor has been conducted is indicated in the following tabulation:

Year	*Entire Run-off to	Minimum Flow in Second-feet		
	San Francisco Bay in Per Cent of Normal	At Colusa	At Sacramento	San Joaquin Near Vernalis
1924	28	1470	705	391
1925	83	1870	2760	660
1926	57	1030	1330	565
1927	114	1960	3420	1290
1928	80	1960	2510	840
1929	42	1550	2300	565
1930	63	1680	2350	645

\* Normal is 40-year mean (1889-1929) of natural run-off at foothill stations of major tributaries. Previous reports have given run-off in per cent of 50-year mean (1870-1920) as given in Bulletin Number 5, Division of Water Resources.

It will be noted that as far as the seasonal run-off is con-

cerned, 1930 was little better than 1926. However, the 1930 rice acreage was considerably less than that of 1926 and the minimum stream flow which occurred, similar to that of 1928 and 1929, was not critical as in 1924 and 1926. No serious navigation difficulties or shortages of water for irrigation purposes were reported in 1930 and the encroachment in the Delta of salinity to the extent of 100 parts of chlorine per 100,000 corresponded closely with the encroachment of 1928 and 1929. In 1930, therefore, the requirements for strict conservation measures and regulation of diversions through the Water Supervisor's office were somewhat modified, and the work was confined largely to the engineering investigation dealing with the collection of required hydrographic data and records.

## CHAPTER II

## MEASUREMENTS OF STREAM FLOW

During the irrigation season of 1930, stream flow measurements and records have been obtained through cooperation with the Water Resources Branch of the U. S. Geological Survey for stations on the Sacramento River at Kennett, Red Bluff, Butte City, Colusa, Knights Landing, and Verona; on the Feather River at Nicolaus; on the American River at Fair Oaks and "H" Street Bridge, Sacramento; on the Mokelumne River at Woodbridge and Thornton; and on the San Joaquin River near Vernalis and Newman. Supplementing these, the Water Supervisor has maintained additional stations on upper Butte Creek one mile west of the East Side Highway, on lower Butte Creek and Butte Slough, and in connection with the San Joaquin return water measurements (See Chapter IV) stations as follows: Stanislaus River at Orange Blossom Bridge and at Elliot Ranch, Tuolumne River at Roberts Ferry Bridge and at Tuolumne City, Merced River at Yosemite Valley Railroad Crossing and at the bridge on Hills Ferry Road, Dry Creek at Old Waterford Bridge and at Basso Ranch (near Modesto), and San Joaquin River at San Luis Island and at Grayson (Laird Slough).

Ac. Ft. for Month	1267000	536000	186000	165000	311000	415000

NOTE: This represents the flow past Sacramento (below the City of Sacramento intake) to the Delta. The discharges of this table have been computed by adding to the measured Verona discharges the measured inflow of return water and American River and subtracting therefrom the measured diversions between Verona and Sacramento. A gaging station is not maintained at Sacramento because of tidal action.

NOTE: Gaging station located at Durham Ferry Bridge below the junction of Stanislaus and San Joaquin Rivers. Station maintained by Water Resources Branch of the U. S. Geological Survey under cooperative agreement.

## CHAPTER III

## MEASUREMENT OF DIVERSIONS

Measurements and records of diversions in 1930 have included those from the Sacramento River and its tributaries within the valley floor, those to the Delta Uplands from San Joaquin River, Old San Joaquin River and Tom Paine Slough and those on the Stanislaus, Tuolumne, Merced, and San Joaquin Rivers and Dry Creek as obtained in connection with the return water measurements (See Chapter IV). This report records a total of 493 diversions, segregated to the various sources as follows: Sacramento River 251, Colusa Trough 11, Back Borrow Pit (carrying drainage water from Colusa Basin along the back levees of Reclamation Districts 108 and 787) 5, Lower Butte Creek and Butte Slough 16, By-pass and Drainage Channels 13, Feather River 37, Yuba River 6, American River 29, diversions to Delta Uplands from Old San Joaquin River 11, from Tom Paine Slough 7, from San Joaquin River (below Durham Ferry Bridge) 30, and from Cache Slough 1, San Joaquin River (above Durham Ferry Bridge) 18, Stanislaus River 11, Tuolumne River 9, Dry Creek 7, and Merced River 31.

Under the system for obtaining the diversion records, pump operators have kept daily records on blanks furnished by the Water Supervisor. These records are collected monthly by the field engineers at the same time that the readings of the electric meters are recorded. In order to establish the relation between power input and water pumped, as many as possible current meter measurements of discharge are made throughout the season. With the daily operation records available it has been possible to compile from the monthly diversions as computed

from the power record, a daily diversion record for each plant. In this report and the tables of this chapter it is only possible to publish the record of monthly diversions for each plant. However, the daily diversion records have been compiled as a supplemental report and this is on file and available for reference in the office of the Division of Water Resources.

- (1) New installation 1930.
- (2) Formerly listed as California Bank and Trust Company.
- (3) Formerly listed as 12" pump.
- (4) Replaces 8" unit.
- (5) This plant pumps water to the irrigation canal both from a drain canal of District 1000 and from the Sacramento River. The diversions listed are those from the river only. The water obtained from the drain canal was as follows: (Acre-feet) April 480, May 1504, June 901, July 1086, August 1303, September 817, October 43, Total 6134.

(6) The total diversion shown for this plant together with a portion of the diversion by the plant at Mile 22.5 R was by-passed to the east borrow pit of the Yolo By-Pass to be repumped on to By-Pass lands. (See "Yolo By-Pass Diversions" - Fisher and Rich).

(7) 5" gas outfit replaced in June by 6" electric.

\* Mileage along river above Southern Pacific Bridge, Sacramento.

(1) The diversion by this plant was used in conjunction with a portion of the diversion from the plant at Mile 22.5 R to irrigate the acreage reported for the latter plant.

(2) Cross Canal, the main drain between R.D.1000 and 1001 joins the river at Mile 19.6 L. At the mouth of this drain Natomas Northern Mutual Water Co. maintains, during the irrigation season, a booster pump supplying water from the river to the drain. The water is retained in the drain by a movable dam at its mouth. When the river falls lower than the crest of this dam the gates are closed and the booster pump started. There are pumping plants along the south bank of Cross Canal, but only one, at Mile 4.0 from the mouth, was operated in 1930 and the acreage shown was irrigated from this plant. From April 5th until June 11th, inclusive, water was available in Cross Canal without pumping at Booster Plant. The diversions here shown are those for the plant at Mile 4.0 on Cross Canal from April 5th to June 11th and for the booster plant for the remainder of the season. The water pumped through the plant at Mile 4.0 was as follows: (Acre-feet) April 2813, May 3636, June 3123, July 3468, August 3302, September 601, Total 16,943.

7. Comparison of River Discharge and Salinity at Bay and Delta Stations, 1930 . . . . .		149

### ACKNOWLEDGMENTS

It is desired to acknowledge and express appreciation for:

The hearty cooperation given by the various engineers, water superintendents, and water users throughout the territory covered by this work;

The cooperation of federal agencies including the Water Resources Branch of the U. S. Geological Survey, through H. D. McGlashan, District Engineer and the U. S. Department of Agriculture, Bureau of Agricultural Engineering, through W. W. McLaughlin, Associate Chief;

The untiring and efficient assistance of the engineers as listed under the organization statement who have been employed on this work during the past year.

ADVISORY COMMITTEE

## PERMANENT COMMITTEE OF THE SACRAMENTO-SAN JOAQUIN RIVER PROBLEMS CONFERENCE

The successful prosecution of the Water Supervisor's work both in stream administration and collection of records may be attributed in no small measure to the backing, advice, and continued interest and cooperation of the Permanent Committee of the Sacramento-San Joaquin River Problems Conference.

This Committee, representative of the water users and other interests involved, was appointed by the First Sacramento-San Joaquin River Problems Conference in January, 1924. Its present personnel is as follows:

Herbert E. White, Chairman, Sacramento	
E. L. Adams, Chico	Manly S. Harris, San Francisco
A. E. Anderson, San Francisco	W. I. Hechtman, Sherman Island
Alden Anderson, Sacramento	Warren H. McBryde, San Francisco
G. A. Atherton, Stockton	R. V. Meikle, Turlock
P. M. Downing, San Francisco	Jesse Poundstone, Grimes
William Durbrow, Grass Valley	F. T. Robson, Vina

ORGANIZATION

Walter E. Garrison - - - - - Director of Public Works

Bureau of Agricultural Engineering, U.S.Department of Agriculture.  
O. V. P. Stout - - - - - Hydraulic Engineer  
Lloyd N. Brown - - - - - Assistant Hydraulic Engineer

## CHAPTER I

## INTRODUCTION

Purpose

The purpose of this report is to make of record the measurements made and data collected through the office of the Sacramento-San Joaquin Water Supervisor during the 1930 irrigation season.

Origin and History of Work

This work was inaugurated in 1924 through the efforts of the first Sacramento-San Joaquin River Problems Conference and its Permanent Committee working with the former Division of Water Rights. The funds for the work in the first year were largely subscribed by the water users but subsequently it has been conducted under legislative appropriations included in the regular biennial budget of the Division. A complete description of the origin and history of this work will be found in the 1924 and 1926 Biennial Reports of the former Division of Water Rights, in Bulletin Number 4 of the same Division, and in Bulletin Number 23 of the Division of Water Resources. The latter bulletin brings together all data and measurements obtained by the Water Supervisor in the five year period, 1924 to 1928, inclusive. The reports for subsequent individual years are mimeographed as the present report, with the plan to again bring all data together in a printed bulletin at the end of the second five year period.

Scope

As outlined in previous reports this work is divided into (1) engineering investigations, measurements and collection of records, and

(2) conservation, waste prevention and such administration of the stream flow as shall fall within the jurisdiction of the Division of Water Resources or be mutually agreed upon by the water users. This report presents chiefly, for permanent record, the results of the engineering investigations. These comprise measurements and records of the diversions of water from the Sacramento, Feather, Yuba, American, Merced, Tuolumne, Stanislaus and San Joaquin rivers within the valley floor and above the Delta; stream flow measurements throughout the territory, largely in cooperation with the Water Resources Branch, U. S. Geological Survey; measurements and records of waters returned to the Sacramento and San Joaquin Rivers; studies of the consumptive use of water in the Sacramento-San Joaquin Delta in cooperation with the U. S. Department of Agriculture Bureau of Agricultural Engineering; an annual census of irrigated areas and crops under all diversions recorded and throughout the Delta; and observations and investigation of the advance and retreat of salinity in the Delta channels and Upper Bays.

#### Organization

The regular organization has included the Water Supervisor, Assistant Water Supervisor, and three assistant hydraulic engineers. The organization for the cooperative Delta investigations under the direction of W. W. McLaughlin, Associate Chief, Bureau of Agricultural Engineering, U. S. Department of Agriculture, has included an hydraulic engineer and one assistant giving full time to field work.

Under the direction of Martin H. Blote, Assistant Water Supervisor, engineers James M. Brockway and Ralph S. Rose have been responsible for the work above Sacramento, the former working from Meridian to Redding

and the latter from Sacramento to Meridian; Engineer Frederick E. Anderson has been responsible for the census of irrigated acreages and crops in the Delta, the work in the Delta uplands and that on the Feather, American, and Yuba Rivers; and engineers Brockway and Rose have carried out the return water and diversions measurements on the San Joaquin River and its tributaries. Major O. V. P. Stout has been in charge of the Delta Cooperative work with Engineer Lloyd N. Brown in resident charge at King Island.

Conservation Features

A comparison of the run-off and water supply conditions in the 1930 season with those of the previous seasons in which the work of the Water Supervisor has been conducted is indicated in the following tabulation:

Year	*Entire Run-off to San Francisco Bay in Per Cent of Normal	Minimum Flow in Second-feet		
		At Colusa	At Sacramento	San Joaquin Near Vernalis
1924	28	1470	705	391
1925	83	1870	2760	660
1926	57	1030	1330	565
1927	114	1960	3420	1290
1928	80	1960	2510	840
1929	42	1550	2300	565
1930	63	1680	2350	645

\* Normal is 40-year mean (1889-1929) of natural run-off at foothill stations of major tributaries. Previous reports have given run-off in per cent of 50-year mean (1870-1920) as given in Bulletin Number 5, Division of Water Resources.

It will be noted that as far as the seasonal run-off is con-

cerned, 1930 was little better than 1926. However, the 1930 rice acreage was considerably less than that of 1926 and the minimum stream flow which occurred, similar to that of 1928 and 1929, was not critical as in 1924 and 1926. No serious navigation difficulties or shortages of water for irrigation purposes were reported in 1930 and the encroachment in the Delta of salinity to the extent of 100 parts of chlorine per 100,000 corresponded closely with the encroachment of 1928 and 1929. In 1930, therefore, the requirements for strict conservation measures and regulation of diversions through the Water Supervisor's office were somewhat modified, and the work was confined largely to the engineering investigation dealing with the collection of required hydrographic data and records.

## CHAPTER II

## MEASUREMENTS OF STREAM FLOW

During the irrigation season of 1930, stream flow measurements and records have been obtained through cooperation with the Water Resources Branch of the U. S. Geological Survey for stations on the Sacramento River at Kennott, Red Bluff, Butte City, Colusa, Knights Landing, and Verona; on the Feather River at Nicolaus; on the American River at Fair Oaks and "H" Street Bridge, Sacramento; on the Mokelumne River at Woodbridge and Thornton; and on the San Joaquin River near Vernalis and Newman. Supplementing these, the Water Supervisor has maintained additional stations on upper Butte Creek one mile west of the East Side Highway, on lower Butte Creek and Butte Slough, and in connection with the San Joaquin return water measurements (See Chapter IV) stations as follows: Stanislaus River at Orange Blossom Bridge and at Elliot Ranch, Tuolumne River at Roberts Ferry Bridge and at Tuolumne City, Merced River at Yosemite Valley Railroad Crossing and at the bridge on Hills Ferry Road, Dry Creek at Old Waterford Bridge and at Basso Ranch (near Modesto), and San Joaquin River at San Luis Island and at Grayson (Laird Slough).

Ac. Ft. for Month	1267000	536000	186000	165000	311000	415000

NOTE: This represents the flow past Sacramento (below the City of Sacramento intake) to the Delta. The discharges of this table have been computed by adding to the measured Verona discharges the measured inflow of return water and American River and subtracting therefrom the measured diversions between Verona and Sacramento. A gaging station is not maintained at Sacramento because of tidal action.

NOTE: Gaging station located at Durham Ferry Bridge below the junction of Stanislaus and San Joaquin Rivers. Station maintained by Water Resources Branch of the U. S. Geological Survey under cooperative agreement.

## CHAPTER III

## MEASUREMENT OF DIVERSIONS

Measurements and records of diversions in 1930 have included those from the Sacramento River and its tributaries within the valley floor, those to the Delta Uplands from San Joaquin River, Old San Joaquin River and Tom Paine Slough and those on the Stanislaus, Tuolumne, Merced, and San Joaquin Rivers and Dry Creek as obtained in connection with the return water measurements (See Chapter IV). This report records a total of 493 diversions, segregated to the various sources as follows: Sacramento River 251, Colusa Trough 11, Back Borrow Pit (carrying drainage water from Colusa Basin along the back levees of Reclamation Districts 108 and 787) 5, Lower Butte Creek and Butte Slough 16, By-pass and Drainage Channels 13, Feather River 37, Yuba River 6, American River 29, diversions to Delta Uplands from Old San Joaquin River 11, from Tom Paine Slough 7, from San Joaquin River (below Durham Ferry Bridge) 30, and from Cache Slough 1, San Joaquin River (above Durham Ferry Bridge) 18, Stanislaus River 11, Tuolumne River 9, Dry Creek 7, and Merced River 31.

Under the system for obtaining the diversion records, pump operators have kept daily records on blanks furnished by the Water Supervisor. These records are collected monthly by the field engineers at the same time that the readings of the electric meters are recorded. In order to establish the relation between power input and water pumped, as many as possible current meter measurements of discharge are made throughout the season. With the daily operation records available it has been possible to compile from the monthly diversions as computed

from the power record, a daily diversion record for each plant. In this report and the tables of this chapter it is only possible to publish the record of monthly diversions for each plant. However, the daily diversion records have been compiled as a supplemental report and this is on file and available for reference in the office of the Division of Water Resources.

- (1) New installation 1930.
- (2) Formerly listed as California Bank and Trust Company.
- (3) Formerly listed as 12" pump.
- (4) Replaces 8" unit.
- (5) This plant pumps water to the irrigation canal both from a drain canal of District 1000 and from the Sacramento River. The diversions listed are those from the river only. The water obtained from the drain canal was as follows: (Acre-feet) April 480, May 1504, June 901, July 1086, August 1303, September 817, October 43, Total 6134.
- (6) The total diversion shown for this plant together with a portion of the diversion by the plant at Mile 22.5 R was by-passed to the east borrow pit of the Yolo By-Pass to be repumped on to By-Pass lands. (See "Yolo By-Pass Diversions" - Fisher and Rich).
- (7) 5" gas outfit replaced in June by 6" electric.

\* Mileage along river above Southern Pacific Bridge, Sacramento.

(1) The diversion by this plant was used in conjunction with a portion of the diversion from the plant at Mile 22.5 R to irrigate the acreage reported for the latter plant.

(2) Cross Canal, the main drain between R.D.1000 and 1001 joins the river at Mile 19.6 L. At the mouth of this drain Natomas Northern Mutual Water Co. maintains, during the irrigation season, a booster pump supplying water from the river to the drain. The water is retained in the drain by a movable dam at its mouth. When the river falls lower than the crest of this dam the gates are closed and the booster pump started. There are pumping plants along the south bank of Cross Canal, but only one, at Mile 4.0 from the mouth, was operated in 1930 and the acreage shown was irrigated from this plant. From April 5th until June 11th, inclusive, water was available in Cross Canal without pumping at Booster Plant. The diversions here shown are those for the plant at Mile 4.0 on Cross Canal from April 5th to June 11th and for the booster plant for the remainder of the season. The water pumped through the plant at Mile 4.0 was as follows: (Acre-feet) April 2813, May 3636, June 3123, July 3468, August 3302, September 601, Total 16,943.

\* Mileage along river above Southern Pacific Bridge, Sacramento.

- (1) See Plant at Mile 80.0 L.
- (2) New installation 1930.
- (3) Additional water was received from the Steidelmeier plant at Mile 71.9 R.
- (4) A portion of the diversions by this plant was used on the Browning land to the south (See Mile 71.9 R).
- (5) October diversion was for stock.
- (6) Formerly 24" - New pump installed.
- (7) Includes adjacent lands irrigated from this plant as follows: Kilgore 32; Stacs 30; Rockholt 20; (62 Reische).
- (8) Includes 38 acres on adjacent lands of Burtis.
- (9) This is the total acreage irrigated from this plant and the other company plants at Miles 67.4 L; 68.81 L; 71.1 L; and 74.8 L. An additional 271 acres were irrigated from the plant at Mile 67.5 and were included in the acreage figure given there.

(1) This is a common point of diversion for the Glenn-Colusa, Jacinto, Compton-Delevan, Provident (partial), and Princeton-Codora-Glenn (partial), irrigation districts, and C. L. Leonard. Refer to the above plants at Mile 154.8 for their respective diversions through this plant.

(2) Includes 795 acre-feet obtained by gravity in April. Diversions in November and December were 8040 and 1600 acre-feet, respectively. Additional water was obtained by gravity from Stony Creek as follows: (Acre-feet) April 1795, May 430.

(3) Same plant as that of Glenn-Colusa Irrigation District.

(4) See Plant at Mile 124.2 R.

(5) See Plants at Miles 112.4 R and 123.9 R.

(6) An additional 18 acre-feet diverted in November.

(7) Formerly listed as George Butler.

REDDING-ALTURAS BRIDGE	MILE 242.0																			

\* Mileage along river above Southern Pacific Bridge, Sacramento.  
 (1) Formerly Johnson and Coates.  
 (2) Formerly L. C. Smith.  
 (3) Includes 25 acres served by plant at Mile 240.5 L.  
 (4) An additional 25 acres was irrigated for Menzel Meat Company. See plant at Mile 240.2 L.  
 (5) Corrected mileage.

TABLE 15 (CONTINUED)

SACRAMENTO RIVER DIVERSIONS

Water User	*Mile and Bank of Pump	Number and size of Pump	Monthly Diversions in Acre-feet												Total	Acreage Irrigated

<b>TOTALS</b>			74236	198836	221852	217698	199875	107577	32681	1052755	96577	56184				

\*Mileage along river above Southern Pacific Bridge, Sacramento.

(1) Corrected mileage.

(2) This pump runs practically continuously throughout the irrigation season but excess water runs right back to river through gardens. Actual seasonal diversion by the pump was 550 acre-feet but the use for the 30 acres is estimated at 5 acre-feet per acre or 150 acre-feet as shown.

(3) Some of this diversion returns to the Sacramento River through the Creek channels between Redding and south of Cottonwood as seepage and direct spill. Observations of this return flow were made at various times and estimated as follows: (Acre-feet) April 2500, May 3600, June 2000, July 4000, August 4000, September 3800, October 3000, Total 22900.

\* Approximate mileage along creek from junction with Sacramento River.  
 (1) Served also by plant on Sacramento River at Mile 112.1 L and diversion from Butte Creek at Mile 9.3 R.  
 (2) Includes 100 acres served by P. V. Berkeley plant on Sacramento River at Mile 89.3 L.  
 (3) Prior to September 1st some of the diversion at Mile 9.3 R was used for the 565 acres of general crops and 175 acres rice.  
 (4) Prior to 1930 no data was secured relative to gun club acreage other than that served by pumping prior to Sept. 1st. The clubs grouped under this heading obtain their water by gravity. The estimated acreage flooded on each club follows: White Mallard 650 Ac; Wild Goose 400 Ac; C. Berry 250 Ac; Green Head 500 Ac; Field and Tule 400 Ac; North Butte 300 Ac; Sacramento Outing 650 Ac; Henshaw 200 Ac; West Butte 600 Ac; Colusa 600 Ac.  
 (5) This is opposite approximate center of these clubs.  
 (6) See following plants - Sacramento River Mile 112.1 Left and Lower Butte Creek Mile 3.9 Right.

TOTALS			4803	9234	10293	11752	10825	7137	4477	58521	4680

\* Approximate mileage along river above Highway Crossing at Marysville.  
 (1) This acreage irrigated by Marysville River Farms Company plant at Mile 6.6 Left.  
 (2) Formerly called "Unit #8 Plant".  
 (3) An additional 30 acres irrigated for Wm. Dinsmore at Mile 4.5 Left.  
 (4) Hallwood Irrigation Company and Cordua Irrigation District have a common point of diversion and common canal for about one-half mile; diversion and acreage figures are for combined projects. Irrigated acreage is segmented as follows; Hallwood, Rice 1325, General 3900; Cordua, Rice 1550, General 360.  
 (5) This is a continuous gravity diversion. The water is used on a young orange grove and the surplus is spilled back to the river.

## CHAPTER IV

## MEASUREMENTS OF RETURN WATER

Sacramento Return Waters

In the Sacramento Valley the flow is measured and recorded for all of the well defined channels discharging return water from irrigation back to the Sacramento River. Table 32 lists these channels in downstream order and gives the total flow computed from measurements thereon.

Between Colusa and Red Bluff there are no large well defined return channels. Records or estimates of all natural inflow from streams in this stretch of the river were, however, obtained. Above Red Bluff, on the upper end of the river between Redding and a point below Cottonwood there is a considerable return from the irrigation of the Anderson-Cottonwood Irrigation District. An estimate of this return water is given in the footnote at the end of Table 15, Chapter III.

Return Flow from other than Sacramento River Sources

In the water returned to the Sacramento River as included in Table 32, it should be noted that practically all of that entering the river through Butte Slough is derived from Feather River diversions through the Western and Sutter Butte canals. Of the discharge entering through Sacramento Slough, that portion flowing down the East Borrow Pit of Sutter By-Pass is, also, practically all from Feather River irrigation.

Relation of Sacramento Return Water to Irrigation Draft

Tables 33 and 34 record the Sacramento River return water, June to September, inclusive, 1930, and indicate the relation between the return and the diversions from which it is derived. Since, in these tables,

it is the purpose to show the return water from Sacramento River diversions only, the inflow from Butte Slough, East Borrow Pit of Sutter By-Pass, Back Borrow Pit of Reclamation District 1000 and the Feather and American Rivers has been excluded. In Table 33 is shown the relation to the diversions of that return water only which was actually measured at the well defined channels. With the records available for the discharge of the Sacramento River at Red Bluff, Butte City, Colusa, Knights Landing, Verona and Sacramento, and all diversions between those points recorded, as well as the inflow from the Feather and American Rivers, it is possible to compute what should represent the total water returned to the river between each of those points, including not only the flow in the definite channels which were measured, but all seepage, groundwater return, etc., which cannot be directly measured. The figures for the return water as computed in this manner and the relation of this return to the draft are shown in Table 34. A comparison of Tables 33 and 34 shows that seepage, groundwater return, etc., which cannot be directly measured, amounted to 25 per cent of the irrigation draft in the period June to September, inclusive, while the direct return measured in definite channels totaled 30 per cent of the draft. The total return amounted to 55 per cent of the draft. Plate 1 is a diagram showing the accumulated irrigation draft and return water in downstream order, Red Bluff to Sacramento, for the four months' period, June to September, 1930.

#### Draft-Return Water Relation for Particular Sacramento Valley Areas

In the Sacramento Valley there are certain units or districts which are so set apart physically by levees or otherwise that the return water in each district may be readily segregated. In each case the

records of all diversions to and discharges from the unit are available. Such units are, the area above the Colusa-Williams Highway Crossing of Colusa Trough, Reclamation District 108, and Reclamation District 1500. The relation between the 1930 draft and return water for the Colusa Trough area is shown in Table 35 and for Reclamation Districts 108 and 1500, in Tables 36 and 37, respectively.

Tables 38 to 49, inclusive, present in detail the discharge measurements for the Sacramento Valley return water channels.

#### San Joaquin Return Waters

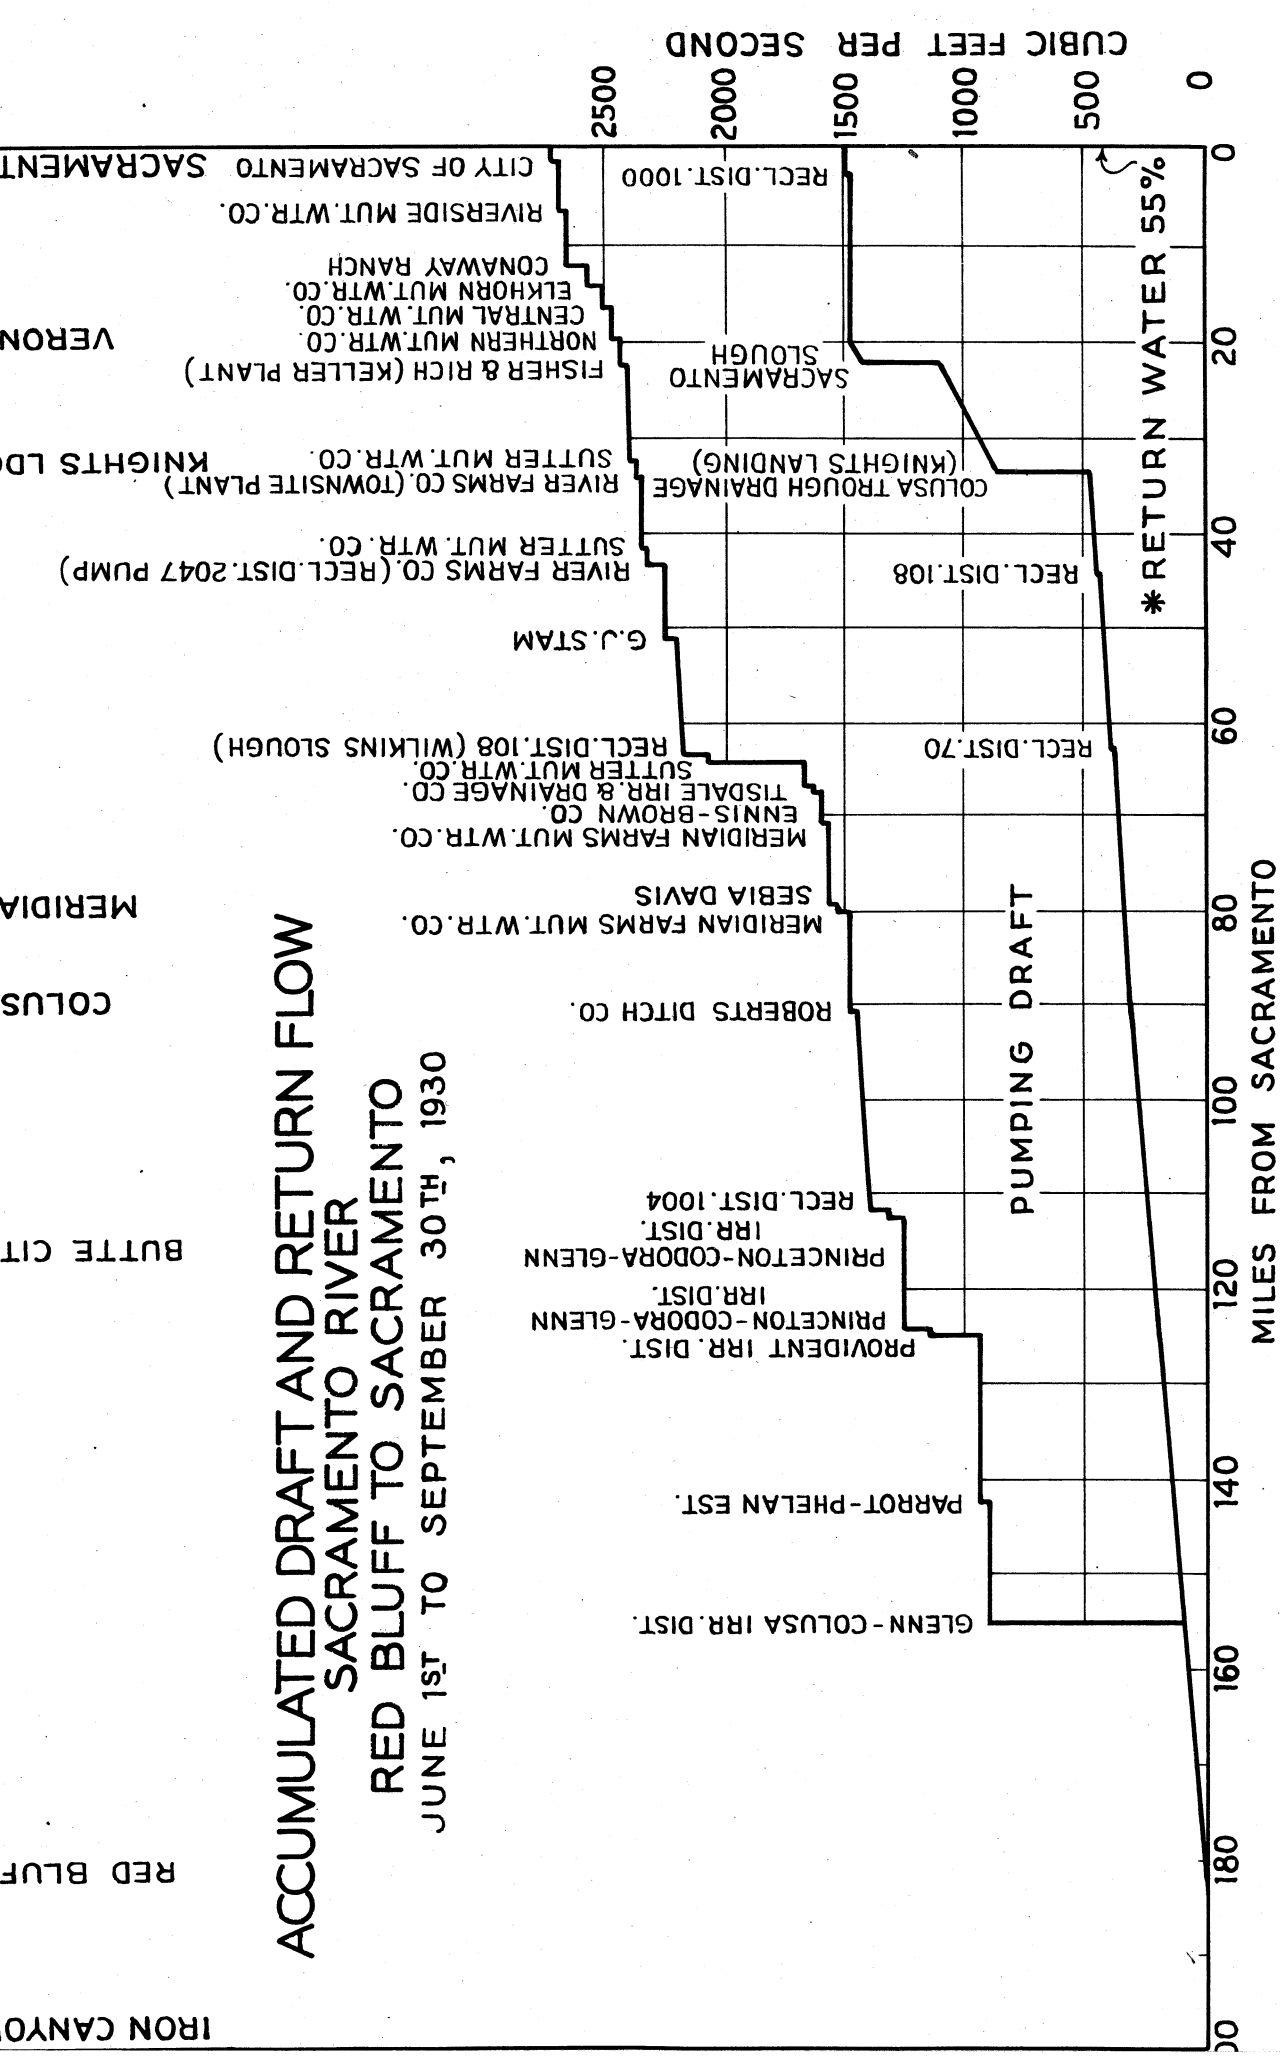

In the San Joaquin Valley return water measurements of 1930, the gaging stations were located at the same points as in 1929 and the same methods were followed. That is, a continuous record of the discharge from June to September, inclusive, was secured at an upper and lower station on each stream: San Joaquin, Stanislaus, Tuolumne, and Merced Rivers, and Dry Creek. On the San Joaquin River, continuous records of discharge were also obtained for intermediate stations, one near Grayson (Laird Slough) and the other just below the junction with Merced River. The latter is a station maintained by the U. S. Geological Survey and referred to as "San Joaquin River near Newman". Measurements and records of all pumping diversions between the upper and lower stations on each stream were also obtained, thereby completing the necessary data for the computation of the return water. Table 50 gives the results of the San Joaquin return water measurements and Table 51 presents a comparison of the return water and irrigation draft for the 1930 season. Tables 52 to 61, inclusive, give the discharge records for the upper and lower stations on each stream. The records of the diversions used in

the computation of the return water will be found in Chapter III, Tables 27 to 31, inclusive.

# ACCUMULATED DRAFT AND RETURN FLOW SACRAMENTO RIVER RED BLUFF TO SACRAMENTO

JUNE 1ST TO SEPTEMBER 30TH, 1930

\* THIS RETURN WATER DIAGRAM SHOWS ALL ACCRETIONS AS TAKEN FROM TABLE 34

NOTE: IN ORDER TO SHOW RETURN WATER FROM SACRAMENTO RIVER IRRIGATION ONLY, THE DISCHARGE TO THE SACRAMENTO RIVER OF THE FEATHER AND AMERICAN RIVERS IS EXCLUDED AS IS ALSO RETURN THROUGH BUTTE SLOUGH, A PORTION OF THE RETURN THROUGH SACRAMENTO SLOUGH DERIVED FROM FEATHER RIVER DIVERSIONS AND THE RETURN THROUGH THE BACK BORROW PIT OF RECL. DIST. 1000.

Return in per														
cent of Draft		74%		44%		42%		64%						55%

\* As the return water in this table between any two stations is computed as the difference in discharge between the upper and lower station, making due allowance for the intervening diversions, the results include both those accretions entering from definite return channels which have been measured and accretions due to seepage, groundwater return, etc., which cannot be directly measured.

NOTE: Computed from record of river discharge at Red Bluff, Butte City, Colusa, Knights Landing, Verona and Sacramento and measured diversions between these points. In the return water here shown the discharge to the Sacramento River of the Feather and American Rivers is excluded as is also return through Butte Slough, a portion of the return through Sacramento Slough derived from Feather River diversions and the return through the Back Borrow Pit of Reclamation District 1000. Also, inflow from Mill, Antelope, Deer and other Creeks between Red Bluff and Butte City has been excluded.

Net Return Water Sacramento River Acre-feet	14200	12000	11300	12100	11400	4860

NOTE: To determine the amount of this discharge that is strictly return water the discharge for the station measuring natural flow in Butte Cr. one mile west of the East Side Highway (See Table 8) is subtracted as shown above.

This return water is practically all from lands irrigated by Feather River diversions, and is measured in a dredger cut which carries the water from Butte Creek to Butte Slough and joins the latter at Mile 0.7 West. Butte Slough joins the Sacramento River at Mile 84 Left.

## CHAPTER V

## USE OF WATER IN THE SACRAMENTO-SAN JOAQUIN DELTA

As outlined in detail in preceding reports this investigation having as its objective a complete annual determination of the consumptive use of water by the entire Sacramento-San Joaquin Delta, has comprised the experimental work to determine the unit consumptive use of water by all water consuming crops and growths in the Delta and the general field work to obtain annually a complete census of the irrigated crops and water consuming areas. With the unit consumptive use of water determined by the experimental work and the complete census available, the former may be applied to the latter to derive the complete consumptive use of water for the Delta as a whole or for individual tracts or islands.

Through the regular Federal-State cooperation for Irrigation Investigations the experimental work has been conducted by the Division of Irrigation, Bureau of Agricultural Engineering, U. S. Department of Agriculture and has included probably as its most successful feature and that furnishing most definite and conclusive results, the consumptive use determinations for various Delta crops and vegetation grown in tanks. In 1930 the cooperative work included investigations of the use of water by barley, onions, celery and weeds grown in tanks on King Island, a continuation of the asparagus tank work on the Richmond-Chase tract, tule and cat-tail tanks on King Island and in Reclamation District 999 near Clarksburg, tule tanks on Simmons Island, Suisun Bay, an experiment on a King Island beet field to determine the effect of various irrigation treatments on the tonnage and sugar content of the beets, and investi-

gation of flooding methods in the removal of alkali and in the elimination of nematodes. This work is presented in detail in the report by Major O. V. P. Stout and Lloyd N. Brown which follows in this chapter.

The annual census of the acreage of irrigated crops and water consuming areas has been made through the regular organization of the Water Supervisor and the data for 1930 are given in Tables 62, 63 and 64.

As an important feature of the Special Studies of Salinity Control and the Salt Water Barrier, conducted as a part of the Water Resources Investigation in the development of the "State Water Plan", it has been necessary to derive the best possible estimate of the consumptive use of water in the Sacramento-San Joaquin Delta. In this derivation all of the data on the Delta experimental work and crop census as given in the Water Supervisor Reports beginning with 1924 and including 1930 have been available and the manner of their use and the complete estimate of the Delta's consumptive use are presented in detail in the Water Resources Investigation Bulletin Number 27 - "Variation and Control of Salinity in Sacramento-San Joaquin Delta and Upper San Francisco Bay". In order to make the complete estimate it was found necessary to obtain certain additional data on the extent of idle and bare lands, the acreage of aquatic growths such as tules, cat-tails, willows, the area of interior water surfaces, etc., and it will be noted that the form of Table 62 in this report has been changed somewhat from that of previous years in order to report these additional data. In accounting for the complete acreage of each tract or island under the various segregations a further and more exact check upon the total acreage figures has been obtained and explains the changes in

these figures from those given in previous reports.

The experimental work is to continue on a small scale in order to bring the investigation of the consumptive use of water by aquatic plants to a satisfactory conclusion, to extend the asparagus tank work to cover the economic life of the plants and to perhaps gain more conclusive data on the use of water by weeds and other such non-economic growths. Under present plans, an office report covering the entire Delta cooperative investigation in detail and presenting the complete estimates for the Delta consumptive use of water is to be completed and submitted by Major Stout in 1931. Subsequently it is planned that the usual census and securing of the other data necessary to continue the annual estimates of the Delta's consumptive use will be continued through the Water Supervisor's office. After publication of Bulletin Number 27 and the submission of the report by Major Stout, it is planned that the annual data and computations and complete estimates of the consumptive use of water will be incorporated as a part of the Water Supervisor Reports, beginning with the 1931 Report.

TABLE 63

SUMMARY OF ACREAGES AND CROPS IRRIGATED IN THE  
SACRAMENTO AND SAN JOAQUIN-MOKELUMNE DELTAS-1930

Crop	Sacramento Delta	San Joaquin- Mokelumne Deltas	Total
Alfalfa	10295	16635	26930

Truck and Miscellaneous) Vegetables )	13328	2006	15334
Totals	119316	193117	312433

NOTE: In the data for similar tabulations in previous years, the boundary between the deltas has been taken as San Joaquin River, North Fork of Mokelumne River and Snodgrass Slough. In this tabulation a more strict division in accordance with drainage lines has been made. With this division the boundary divides Sherman and Andrus Islands and Reclamation District 551.

COOPERATIVE IRRIGATION INVESTIGATIONS  
IN THE SACRAMENTO-SAN JOAQUIN DELTA IN 1930

By

O. V. P. Stout, Hydraulic Engineer,  
Division of Water Resources, State Department of Public Works,  
and  
Division of Irrigation, Bureau of Agricultural Engineering,  
U. S. Department of Agriculture,

and

Lloyd N. Brown, Assistant Hydraulic Engineer,  
Division of Water Resources, State Department of Public Works.

INTRODUCTION

The Cooperative Irrigation Investigations in the Sacramento-San Joaquin Delta in 1930 were confined mostly to the peat lands, where experiments on the use of water by crop and other plants was continued in the same manner as in previous years. Some incidental experiments relating to the irrigation of beets and to flooding to remove alkali also received attention. The nematode plots, where it was undertaken to determine the effectiveness of flooding to eradicate this pest, were also continued.

The record of use of water by tules and cattails in tanks at Clarksburg was carried through the year, and experiments with the same plants, but under more nearly normal conditions of exposure, were inaugurated on King Island and on Simmons Island. The new experiments were undertaken at the instance of the Water Resources Investigation.

At the present time there is an awakening of those concerned with the conservation and utilization of the water resources to the importance of the question of the waste involved in the consumptive use of water by growths which serve no useful purpose. Several agencies have concerned themselves in the matter to the extent of launching investigations.

It may not be too much to say that this is in considerable degree due to results reported from these investigations, and that there rests the obligation that the questions which have been raised should be settled.

### PEAT LAND INVESTIGATIONS

#### SUMMARY

The determinations of consumptive use of water in 1930 were confined to crop and other plants growing in tanks. The reason for this, as noted in the report for 1929, is that the control which is possible in the tank work makes it more definite and therefore more valuable than when results depend upon the measurement of water visibly admitted to and drained from fields of growing crops, without adequate or satisfactory account being reasonably obtainable of the water which moves in and out of the fields by way of underground paths, nor, so far as peat lands are concerned, of the differences in the amounts of water stored in the soil of the fields at the beginning and the end of periods of time considered.

The tanks at Camp  $3\frac{1}{2}$  on King Island contained barley and onions until those crops were harvested in midsummer. The barley yields covered an extensive range, from a minimum corresponding to crop failure up to a maximum greatly in excess of that obtainable in the field. The onion yields were rather less than good average field yield. The relation of consumptive use to yields is discussed in the detailed account to follow.

After the barley and onions had been removed from the tanks eight of them were taken up to be reset and used for tules and cattails, four of them in a tule swamp on King Island and the other four on the shore of Simmons Island, about seven miles northeast of Bay Point.

The outer cylinders of these eight tanks were found to be so badly corroded that they would not stand resetting and had to be replaced by new ones. They had been in service since 1925, with the peat soil of the field against their outer surfaces and water from the channels against their inner surfaces up to the elevation of the water table in the inner or soil cylinder. The corrosion was on the outer surface, the affected belt being bounded by lines corresponding closely to the highest and lowest elevations of the water table in the field.

The asparagus tanks set in 1927 on the Richmond-Chase ranch were continued in service throughout the year in 1930. The lack of anything like a precise correlation between the consumptive use by asparagus and any other of the determined elements still persists, but it has been found possible, in spite of this, to make fairly confident use of the results of the investigation in estimating the consumptive use of water by asparagus in the Delta. The nearest approach to correlation of use and yield appears in the case of yield of tops in 1930. (See Plate 3). If the experiments are continued for an additional period of a few years, sufficient to bring the plants in the tanks to maturity, a better basis of estimate than the present one will be available.

The experiments on King Island, designed to determine the effectiveness of flooding in destroying nematodes, were continued in 1930, and point quite definitely to the conclusion that, so far as continuous and uninterrupted flooding is concerned, an impracticably long period of time is required to eradicate the pest. Some experiments in intermittent flooding should be made, however, in order to determine if more rapid procedure is possible by that method.

Advantage was taken of an opportunity to observe experiments made by the Richmond-Chase Company in flooding asparagus land to leach out whatever injurious salts may be present. The final analysis of these experiments must be made in the light of crop records yet to accrue, but a brief description of the work and a general statement of some of the results to date are included in this report.

The experiments on sugar beet plots on King Island, commenced in 1929 at the instance of Dr. W. W. Robbins, of the California Agricultural Experiment Station, were continued through the season of 1930. An account of the season's work and results is given.

#### TANK WORK

##### Asparagus

Tank work on asparagus began early in 1927 when twelve tanks were installed on the Richmond-Chase ranch near Terminous. The tanks were located in a row running north and south and are numbered from south to north. They are of the same type as used in other work of this nature with Delta crops, but are of a greater diameter. The soil surface in the inner cylinder has an area of 9.28 square feet corresponding to 4694 crowns per acre, a typical asparagus planting. Crowns of the Mary Washington variety were obtained from the University Farm at Davis and female or pistillate plants were set in the odd numbered tanks, and male or staminate plants in the even numbered tanks. It was subsequently found that one of the plants set for staminate was pistillate.

The tanks were divided into three groups for different irrigation

treatments. The water was held at \*two feet below the ground surface in tanks 1 to 4, inclusive; three feet in tanks 5 to 8, inclusive; and four feet in tanks 9 to 12, inclusive. No asparagus was cut during the first two years - 1927 and 1928 - but was cut regularly in the third and fourth years, 1929 and 1930. The cutting seasons lasted from the first appearance of spears until July 1st - the commercial cutting season. Following the cutting seasons the spears were allowed to develop into tops.

In Table 65 are shown the general results of the tanks by groups since the inception of the work. The table is arranged so that the yield of spears is placed with the use of water and weight of tops for the previous season because the plant food stored by the tops in the roots produces the spears the following season. During 1929 and 1930 the falling off of production with the two-foot water table and the increase in production with the four-foot water table are very noticeable. Judging by the weight of tops of 1930, group III will produce the most tonnage again in 1931. In Table 66 are shown the number of spears and their total and average weights. It will be noted that in general the plants grown with the four-foot water table showed increased production in 1930 whereas the tanks with three and two-foot water tables held about even and showed a decreased production, respectively. While all of these figures tend to argue in favor of the four-foot water table, too hasty an acceptance of them as final should not be made because the life of an asparagus plant is from 12 to 15 years and maximum production is not reached until about the eighth or ninth year.

---

\* The depths listed are the nominal depths -- those contemplated in the plan of the work. The depths actually maintained varied somewhat from the nominal, the variation during the season up to about the middle of July being in general small and in both directions, while from that time on to the end of the year the depths were greater than the nominal, the average excess amounting in some instances to as much as half a foot.

\*\* Exclusive of berries.

Table 67 shows the yearly uses of water and weights of tops exclusive of berries.

The item of chief concern in connection with all crops is the relation of use of water to commercial yield of crop, and the amount of water required to produce a crop corresponding to the average yield in a good year. In the case of asparagus it is considered that the relation to be studied is that of the yield of spears in any season to the use of water in the previous year. The reason for this is that the use of water in any calendar year up to the end of the cutting season amounts to very little, and that the spears are derived from plant food stored up when the plant was growing in the fern in the previous year. Plate 4 is a diagram on which the abscissa of any point represents the yield, in tons per acre, of spears from a certain tank in a certain season, and the ordinate to the point represents the corresponding consumptive use of water, in acre-feet per acre, in the previous year from about April to December. The yield of spears in 1929 is plotted against the use of water in 1928 and the yield of spears in 1930 against use of water in 1929, - 1929 and 1930 being the first and second seasons of cutting and the third and fourth seasons of growth in the the tanks.

The rates of yield of spears, in tons per acre, from the tanks are greatly in excess of those which are obtained from the fields. Beyond the fact that tank conditions correspond to a complete stand of plants, whereas field stands fall materially short of being complete, no explanation of the heavy yields from tanks has been found.

Although there appears a general tendency for the points on the diagram to arrange themselves with reference to a line running upward

# RELATION OF USE OF WATER TO YIELD OF SPEARS

and to the right, there is no close or even serviceable correlation to be deduced from the data shown.

A study of Plate 4 brings out that tanks numbers 1, 2 and 3 in 1930 produced less tonnage of spears than in 1929, and also that the use of water in the year 1929 was less than in 1928. That is to say, the production and the use of water were both less for the later period than for the earlier one. Tank number 4 gave a slightly increased yield with less use of water. The water table in these tanks was two feet down from the soil surface.

Each of the tanks, numbers 5, 6, 7 and 8, in which the water table was at three feet, used less water in 1929 than in 1928. The yield of spears in tanks Nos. 5 and 7, which contained pistillate plants, was less in 1930 than in 1929, and the yield in tanks numbers 6 and 8, which contained staminate plants, was greater in 1930 than in 1929.

Each of the tanks numbers 9, 10 and 11, with water table at four feet, used less water in 1929 than in 1928, but in spite of this fact the yield of spears was greater in 1930 than in 1929. Tank number 12, of the same group, also yielded a greater amount of spears but used slightly more water.

Each tank except number 12 used more water in 1928 than in 1929. It is to be remembered in this connection that there was no cutting in 1928 and the plants were permitted to grow and to use water throughout the year from early spring to late fall, while in 1929 there was but little use of water until the plants made some growth following the close of the cutting season on June 30th.

Table 55, on page 105 of the Sacramento-San Joaquin Water Super-

It has been noted that there is very little use of water during the cutting season.

In 1929, from March 14 to July 1, it averaged .26 acre-feet per acre from tanks with the two-foot water table, .10 acre-feet per acre with the thirteen-foot water table, and practically nothing with a four-foot water table. It may be assumed that these amounts may be charged almost entirely to evaporation from the soil surface.

### Onions

Eight tanks were planted to onions on February 20, 1930. They were harvested on July 31, 1930. The record of use of water was begun on April 4. Tanks numbers 1 to 4, inclusive, were planted with White Globe, and 5 to 8, inclusive, with the Australian Brown variety, known locally as "white" and "buckskin", respectively. These two varieties are among those most widely raised in the Delta. The yields from the tanks were only fair, so the use of water is probably low compared to actual field use. Field yields of 400 sacks or more per acre are common. The onion maggot reduced the crop materially in tanks numbers 6, 7, and 8. This pest is quite common in commercial growing, but since the damage is usually small it is tolerated. A sheep herder removed two or three onions from each of four tanks. However, since there were fifteen or twenty onions in each tank it is believed that the loss was estimated quite accurately and taken into account in the figures submitted in Table 69.

The data of Table 69 are plotted in Plate 5 taking as abscissas Y = yield of onions, in 100-pound sacks per acre, and as ordinates U = use of water, in acre-feet per acre. A line has been drawn to show

# RELATION OF USE OF WATER TO YIELD OF ONIONS

ONION TANKS - KING ISLAND

1930

the use-yield relation indicated, the equation of the line being  $U = 0.00217 Y + 0.85$ . Various growers estimate the average yield of the usual varieties in a good year to be from 150 to 275 sacks per acre. There is one variety, not generally grown, on account of not being a good "shipper and keeper" that yields from 600 to 800 sacks per acre in a good year. According to the results from tanks in 1930, an average yield of 250 sacks per acre would use an average of 1.39 acre-foot of water per acre. The use reported in 1930 to the Water Resources Investigations exceeds this by 0.21 acre-foot per acre, and covers the probability that use in relation to yield may be greater in some years than it was found to be in 1930, the single season in which experiments were made; and also the fact that the average yield estimated above at 250 sacks per acre does not cover the less usual and higher yielding variety or varieties.

Barley

Twenty tanks at Camp Number 3<sup>1</sup>/<sub>2</sub> on King Island were planted to

barley on February 20, 1930. The grain was harvested on June 24th. The record of use of water dates from April 5th. A notable feature of this experiment is the unusually high yield, eight of the tanks producing at the rate of over 100 sacks per acre, each sack weighing 100 pounds. A yield of 40 sacks per acre in the Delta is considered high. However, in commercial production a great deal of grain is lost by lodging and separator waste. If these losses could be prevented, considerably larger crops would be obtained but even then the yield would not approach the heaviest from tanks. The yield of grain, in sacks to the acre, and the use of water, in acre-feet per acre, are shown in Table 70.

TABLE 70

## USE OF WATER AND YIELD, BARLEY TANKS, KING ISLAND, 1930

Tank Number	Yield of Grain 100 LbSks. per Acre.	Use of Water Acre-foot per Acre.
9	118	2.31
10	117	2.29
11	128	2.33
12	132	2.42
13	123	2.28
14	129	2.31
15	132	2.24
16	110	1.92
17	62	1.21
18	27	0.71
19	50	1.31
20	19	0.65
21	20	1.15
22	30	1.17
23	3	1.04
24	47	1.47
25	15	1.46
26	74	1.56
27	72	1.59
28	78	1.62

The data of Table 70 are plotted on Plate 6 and then, excluding all points representing yields of 20 sacks per acre or less, which dispose themselves irregularly, the remaining points are marked off in groups of four, according to the yield represented. The centroid of each group is obtained and a line adjusted to them, having the equation  $U = 0.0136 Y + 0.583$ . For use in estimating the water required to produce a certain yield it may be prudent to increase the constant term in the equation, making it  $U = 0.0136 Y + 0.80$ . According to this equation, the estimated water requirement for a yield of 25 sacks per acre would be 1.14 acre-feet per acre, and for a yield of 40 sacks per acre it would be 1.34 acre-feet per acre.

It is to be borne in mind that the figures just given are based on the results of one season of observation, the only one available covering approximately the entire growing season of grain in the Delta. Experiments elsewhere by others indicate that the figures given should be increased somewhat in estimating consumptive use of water by grain in the Delta.

It is believed, in fact, that the increase should be in material amount, so that the figures for grain and grain hay in general in the Delta will at least closely approximate 1.70 acre-feet per acre, as reported to the Water Resources Investigations. This opinion is based largely on the figures presented in the following tabular statement of the consumptive use of water which various sets of experiments indicate as necessary to produce 2500 pounds per acre of wheat and barley. Consideration is given also to the fact that reported experimental yields are total yields, whereas waste must be added to commercial

field yield in order to obtain total yield. That waste in the field is material in amount appears on viewing the luxuriant volunteer crops of grain which grow up the next year on stubble fields if permitted to do so. In fact, the waste of one season is frequently depended upon in the Delta to seed the ground for the crop of the next season.

Lodging, shelling and separator inefficiency all contribute to the volume of waste of grain. The sack of grain may weigh from 96 to 110 pounds. It has here been taken as 100 pounds.

In general the figures given in the following tabular statement are the results of correlation and computation applied to data presented in the references noted. The yield of 2500 pounds per acre with corresponding use of water does not precisely appear in most of the references. In a number of instances transpiration only is given and evaporation estimated at 0.50 acre-foot per acre must be added to give consumptive use.

Evaporation from bare ground in the Delta during the growing season of grain has been estimated in the report to Water Resources Investigations as amounting to 0.35 acre-foot per acre. The estimate of 0.50 acre-foot per acre for evaporation from grain fields in the same period is not necessarily inconsistent with the estimate for bare ground, for as against the shade and diminished air circulation induced by the crop is the fact that in an irrigated grain field the ground surface will usually be moister than in the bare areas, the ground surface will usually have less the nature of a mulch, and the water table will be higher. Moreover, the intercept of use-yield lines on the use axis is such as to indicate that the allowance of 0.50 for evaporation in grain fields is not too great.

Utah Agricultural College Experiment Station. Bulletin No. 117. The Yields of Crops with Different Quantities of Irrigation Water. John A. Widtsoe and L. A. Merrill. (1912) Experiments with plots. Work done in period 1902-11.		
Use-yield observations when plotted do not show the linear correlation ordinarily found in tank experiments: For wheat, assume evaporation = 0.50 acre-feet per acre: and draw line from point corresponding to that value on the use axis to the lowest placed plotted observation, as obtained from table on page 77, thus assuming linear correlation up to that point. This line gives: - - -	1.80	
The data on barley, as given in the table on page 84, are so irregular as to be useless in this connection.		
Tank experiments with wheat and barley at Davis, Calif. in 1913.		
Notes of unpublished work, obtained from Professor S.H. Beckett. Only four experiments with each crop being of nature to be available for correlation. Deduced: - -	1.75	1.09

Celery

After the onions were harvested, celery plants were set in the same tanks. It was realized that such a late planting might not attain maturity. The celery would have matured sometime in January but it was destroyed by sheep in December. The estimated growth at the time of destruction was about 60 per cent. In Table 72 are shown the results for 1930, and also for 1927, the other year when celery was grown in tanks. It is apparent that if the plants had matured in 1930, they would have used about the same amount of water as was used in 1927.

TABLE 72

USE OF WATER, CELERY TANKS,  
KING ISLAND, 1930 AND 1927

Tank Number	Use of Water	
	1930*	1927
	Acre-feet per Acre	
1	0.70	0.71
2	.76	.83
3	.65	1.10
4	.72	.91
5	.61	1.10
6	.76	1.39
7	.74	.74
8	.80	1.45
Av.	.72	1.03

\* It is estimated that the use of water given in the table for 1930 is from 60 to 70 per cent of what would have been required for full growth and maturity of the crop.

### Weeds

After the barley was harvested, young weeds were dug up and transplanted to the twelve Davis tanks. Since the season of record did not begin until early August the results are to be appraised and used with that fact in mind. The weeds averaged about 6 inches high when they were transplanted from the surrounding barley stubble. At the end of the growing season the growth of the plants in the tanks was estimated as a certain percentage of normal plants i.e., as they grow in the fields. Such estimates ran from 20 to 100 per cent as shown in Table 73.

This table shows the actual use of water by the plants set in the tanks, and also presents rough estimates of the amount of water used by average or normal plants of the same kind growing in the adjacent stubble field at the same time. In making the rough estimate by method

TABLE 73

USE OF WATER BY WEEDS GROWN IN TANKS,  
KING ISLAND, LATE IN SEASON OF 1930

Tank No.	Name of Plant	Aerial Part of Plant	Plant of Normal Field Plant	Esti- mated Ratio of Size of Tank	Use of Water by Tank	Rough Estimate of Use of Water by Field Plants
		Grams	Field Plant	Normal Field Plant	Acre- feet per Acre	Method No.1 : Method No.2 : Acre-feet per Acre
17	Chenopodium anthelminticum.	141.5	0.40	0.90	2.25	2.00
18	Solanum nigrum. Black nightshade.	81.8	0.40	0.69	1.73	1.48
19	Chenopodium album. Lamb's quarter.	30.0	0.25	0.49	1.96	1.26
20	Amaranthus graecizans. Tumble weed.	105.4	0.30	0.56	1.87	1.37
21	Sanchus oleraceus. Sow thistle.	308.1	1.00	1.09	1.09	1.29
22	Echinochloa crusgali. Water grass.	66.9	0.30	0.40	1.33	0.83
23	Xanthium canadense. Cockle burr.	143.2	0.25	0.84	3.36	2.66
24	Polygonum acre. Smart Weed.	150.0	0.25	1.03	4.12	3.42
25	Chenopodium anthelminticum.	250.5	1.00	1.48	1.48	1.68
26	Amaranthus graecizans. Tumble Weed.	68.9	0.20	0.55	2.75	1.75
27	Echinochloa crusgali. Water grass.	53.1	0.40	0.59	1.48	1.22
28	Sanchus oleraceus. Sow thistle.	331.7	1.00	1.42	1.42	1.62

No. 1 the use by the tank plant was divided by the estimated ratio of the size of tank plant to size of normal field plant. In method No. 2 the use by the tank plant was decreased by 0.30 acre-foot per acre, the remainder divided by the estimated ratio of the size of tank plant to size of normal field plant, and 0.50 acre-foot per acre added to the quotient. Method No. 2 presumably gives the better estimate. It will be noted that where plants of the same kind were grown in two tanks, the two corresponding estimates do not agree, whichever method is used. This is not surprising, in view of the fact that some principal elements of the computation are mere estimates. It is believed, however, that the figures presented can be used as an aid to the judgment in any given case. The principal value of the table lies in the indication which it furnishes as to which weeds are the heavy users of water.

#### Tule and Cat-tail

It was decided during the early part of July, 1930, to install some tanks to determine the use of water by tules (*scirpus lacustris*) and cat-tails (*typha latifolia*). Two groups of tanks of four each were put in operation - one set on King Island and the other on Simmons Island. The tanks at both locations were set in patches of the same kinds of plants as were transplanted to the tanks, the idea being to expose the tank plants to as nearly as possible the normal amount of air and sunshine.

The tanks at King Island were located at Camp 3. Tules were placed in two tanks and cat-tails in the other two. The high level of ground water made it impracticable to install the tanks in the usual manner. The method used was to dig around and lift out a core of earth and roots about 15 inches deep. The hole was then dug deep enough to admit the

tank, which was then put down and partially filled with earth. Then the core of earth was lowered into it. The tanks were filled so that when the core was in place the ground surface was about 15 inches below the rim of the tank. Care was taken to disturb the surrounding tule and cat-tail growth as little as possible.

The tanks at Simmons Island were installed in practically the same manner, except that tops of tanks are about two and one-half feet above the ground surface, which is at about the same elevation inside as outside of the tank. The tule growth here was considerably lighter than at King Island, probably due principally to the greater salt content of the water. All four tanks at Simmons Island contain tules - no cat-tails.

The tanks on King Island used a great deal more water than those on Simmons Island, as shown in Tables 74 and 75.

The data at Simmons Island are not as complete as at King Island, and use of water by months has not been computed.

#### Allowance for Rainfall

In the computation of the use of water by crops, a rainfall of 0.25 inch or less, falling on a dry soil surface, has not been counted, and about 0.25 inch has been deducted from heavier rainfalls, falling on dry soil, before taking them into account. This is in accordance with a common practice, designed to allow for the temporarily accelerated rate of evaporation from the soil surface under such conditions. In the case of aquatic plants in tanks, where the top soil was always either covered with water or in a practically saturated condition, the full measure of the rainfall was taken into account in reckoning consumptive use.

2	Ground surface	1.15
3	One foot above ground surface	0.88
4	Ground surface	0.99

## FIELD EXPERIMENTS

Sugar Beet Plots\*

This experiment was designed to determine the effect of various irrigation treatments on the tonnage and sugar percentage of beets. It has run through the crop seasons of 1929 and 1930. The set-up provides for maintaining of the water table at different depths on the different plots. In 1929 there was but one set of plots, but in 1930 a duplicate set was installed. Table 76, setting forth the results of the 2 years' experiments, shows the percentage of sugar and the yields in tons per acre.

TABLE 76

IRRIGATION EXPERIMENTS ON SUGAR BEETS IN PEAT PLOTS,  
KING ISLAND, 1929 AND 1930

Plot	1930				1929		
	Water Table Below Surface Feet	Average Weight per Beet Pounds	Sugar Per Cent	Beets per Acre Tons	Sugar Per Cent	Beets per Acre Tons	
1	1.5	1.83	8.5	31.0	10.1	40.1	
2	2.0	2.18	12.5	35.4	11.0	36.7	
3	2.4	2.02	13.7	31.4	11.1	36.3	
4	2.9	1.93	12.7	29.8	10.0	36.8	
5	1.5	1.81	12.1	28.8			
6	2.0	1.93	13.8	29.4			
7	2.4	1.91	14.7	33.6			
8	2.9	1.93	13.8	32.6			
Average of Replications							
1 & 5	1.5	1.82	10.3	29.9			
2 & 6	2.0	2.05	13.2	32.4			
3 & 7	2.4	1.96	14.2	32.5			
4 & 8	2.9	1.93	13.3	31.2			

\* This experiment was headed by Dr. W. W. Robbins of the University of California Agricultural Experiment Station at Davis, who supervised sampling and weighing the beets and testing them for sugar. The junior writer designed and operated the irrigation system and supervised its installation. All cost and expense was met from funds at the disposal of Dr. Robbins.

The plots were irrigated twice during the growing season of 1930, i.e., the water table was brought up to within about 1.3 feet from the ground surface and held there until the water in the soil above this level was materially increased. At no time did the beets in any of the plots show any signs of suffering for water. The results obtained in 1930 indicate certain trends under the conditions of the experiment. It appears that a water table at about two to two and one-half feet from the ground surface produced the most satisfactory crop since both the sugar percentage and tonnage were higher in this region. The reduced tonnage in 1930 as compared with 1929 is due, inferentially, to the continued production of beets on the same soil.

#### Flooding Peat Land to Remove Alkali

Some areas on the Richmond-Chase ranch have not been yielding as much asparagus as they should. It was presumed that the presence of alkali was responsible for the difficulty. Consequently it was decided to flood two fields of approximately 60 and 70 acres, respectively, to see if the alkali could be removed in this manner.

Eighteen sampling points were located in the 60-acre field and twenty points in the 70-acre field. Thus each sampling point represented about three and one-half acres of land. A set of samples was taken at each point both before and after flooding; and consisted of three sixteen-ounce cans of soil, one can filled at the surface, the second down 22 inches and the third down 44 inches. Vented cans were used so that they could be forced into the soil, thus obtaining an undisturbed sample.

The samples were taken to the laboratory and tested for alkali. The results of the tests have not been completely worked up or analyzed

as yet. However, a preliminary examination discloses that a very large percentage of the alkali was removed. The crop records, while not yet complete, tend to show that the flooding will increase the yield.

#### Nematodes

It appears in the reports of the earlier years of this investigation that the activities of the garden nematode (*caconema radiculicola*) constituted a menace to results. In seeking for means of control or protection, it was found that in the literature of the subject the expedient of flooding the infested fields with water was frequently mentioned as a promising one. Accordingly an area 120 feet by 24 feet, on King Island, was prepared for flooding, and subdivided into 20 plots, each 12 feet square. They were first flooded on July 18, 1928, the water supply being so arranged that there was constant submergence from that time on except as some of the plots were drained for examination and test for the presence of nematodes. It was found that about four months of flooding killed the mature individuals, but that the eggs, or at least a part of them, which were present in the soil, remained fertile for nearly two years, and hatched when the plots were drained at a time of year when temperature conditions were favorable. Thus it appears that continuous flooding is not a suitable method for extermination of this pest. Intermittent flooding, designed to destroy the living organisms, then to hatch the eggs and destroy the resulting individuals before they have time to reproduce, has been suggested, but has not been tried.

SEDIMENTARY LAND INVESTIGATIONS

## TANK WORK

Tules and Cat-tails

In June, 1929, tules and cat-tails were transplanted to tanks in Reclamation District No. 999, near Clarksburg, and the use of water from each tank up to the end of November was determined. The amount of water used was astonishingly large in amount.\* It was therefore decided to leave the plants in the tanks and to continue observations through the year of 1930. The results are set forth in Tables 77 and 78.

These tanks are set in an open field, the only limitation to complete exposure being some small nearby roadside trees which may break slightly the force of a northeast wind. It is believed that the difference in exposure between these tanks and those containing aquatic plants on King and Simmons Islands is the chief factor in accounting for the great difference in consumptive use of water.

RAINFALL RECORDS

Table 79 presents the records of rainfall which have been used in computation of the consumptive use of water. In the records King-Bishop Bridge, Terminous and Clarksburg, the rainfall is recorded for the day on which it fell. The same is true of the Simmons Island record to October 10th, inclusive. At Camp 3, King Island, and for the period after October 16th at Simmons Island, there were no resident observers, and the rainfall noted in each instance is that found in the gage on the date noted, and

represents the accumulation since the date of the visit next preceding.

The top diameter of the larger rain gage at Simmons Island is 8 inches, and of the inner cylinder two and one-half inches. The top is 25 inches above the ground surface on the crown of the low levee. The top diameter of the smaller gage is 3 inches, the inner cylinder being inaccessible for measurement. The gage is mounted on a post, the top of gage being four and one-half feet above ground surface on the crown of the levee.

#### EVAPORATION RECORDS

The evaporation pan at Camp 3 $\frac{1}{2}$ , King Island, is a duplicate of the one at Clarksburg, hereinafter described. Except as annual crops and field weeds grow up around it and perhaps shelter it slightly, it is subject to complete exposure. Observations in 1930 were begun on May 13. Table 80 sets forth the evaporation by months, as determined by plotting the data and interpolating. Rainfall was taken into account on the basis of the record of precipitation at the King-Bishop bridge, about two miles distant, until October 12th. After that date a record kept at Camp 3, somewhat less than a mile distant, was used.

TABLE 80

EVAPORATION FROM FREE WATER SURFACE IN A TANK,  
KING ISLAND, MAY 13TH TO DECEMBER 12, 1930

Month	May 13-31	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec. 1-12	Total
Evaporation: (Feet)	0.23	0.62	0.73	0.62	0.38	0.30	0.21	0.04	3.13

The evaporation pan and rain gages which had been maintained by the U. S. Army Engineers on Simmons Island were reset on October 16th, and observations made and recorded for the remainder of the year. The nominal diameter of the Simmons Island evaporation pan, which is approximated closely by the actual diameter, is 3.5 feet, and the depth is 18 inches. It is mounted on a grillage slightly above the ground surface on the crown of a low levee. A needle point is set in the center of the pan, at elevation about 0.30 foot below the rim of the pan. Observations are made weekly, note being made of the amount of water required to be added in the pan to bring the water surface up to the elevation of the needle point. There is complete exposure to sunlight, and to wind from all directions. The pan is made of galvanized iron, and the exterior surface has rusted up to within about 4 inches of the rim of the pan. The record of evaporation was begun on October 16th. The accumulated evaporation from that date to each of the dates named below was as follows: October 23, .095 foot; October 30, .182 foot; November 6, .255 foot; November 20, .373 foot; December 29, .586 foot; February 19, 1931, .771 foot. By plotting these data and interpolating on the curve through the plotted points, the evaporation by months is obtained, as set forth in Table 81.

TABLE 81

EVAPORATION FROM FREE WATER SURFACE IN A TANK,  
SIMMONS ISLAND, OCTOBER 16TH TO DECEMBER 31, 1930

Month	Oct. 16-31	November	December
Evaporation (Feet)	0.19	0.25	0.15

A record of evaporation from the free water surface in a galvanized iron pan a few feet from the tule and cat-tail tanks near Clarksburg, Reclamation District 999, was obtained for the period June 3d to December 20, inclusive, in 1930. The evaporation by months and for the entire period, as computed from this record, is presented in Table 82. This evaporation pan has a diameter of 2.86 feet, depth 2.45 feet. It is set in the ground, with the rim of the pan slightly less than 6 inches above the ground surface. The exposure is not quite complete, as there is a little early morning shade from a small roadside tree, a road embankment about 50 feet east is a little higher than the pan, and across the road to the east is a young bearing orchard.

TABLE 82

EVAPORATION FROM FREE WATER SURFACE IN A TANK, NEAR CLARKSBURG,  
RECLAMATION DISTRICT 999, JUNE TO DECEMBER, INCLUSIVE, 1930

Month	*Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	*Dec.	Total
**Evaporation (Feet)	0.687	0.704	0.637	0.412	0.276	0.193	0.082	2.991

\* Evaporation for the first three days in June and the last eleven days in December was estimated.

\*\* In allowing for rainfall, the record of precipitation at the headquarters of the Holland Land Company, about one mile distant, was used.

## CHAPTER VI

## SALINITY

As noted in the 1929 report, the Division of Water Resources began a special salinity investigation in June, 1929, as the basis for an exhaustive and conclusive report of the salinity situation, this report to be submitted as one of the series of bulletins on the State Water Plan. This bulletin is to present in detail both the field and office studies conducted since June, 1929, together with analyses and conclusions on the whole salinity situation. This chapter of the present report, therefore, is confined to a presentation only of the field data obtained in 1930 corresponding to a continuation of the established investigations of previous years.

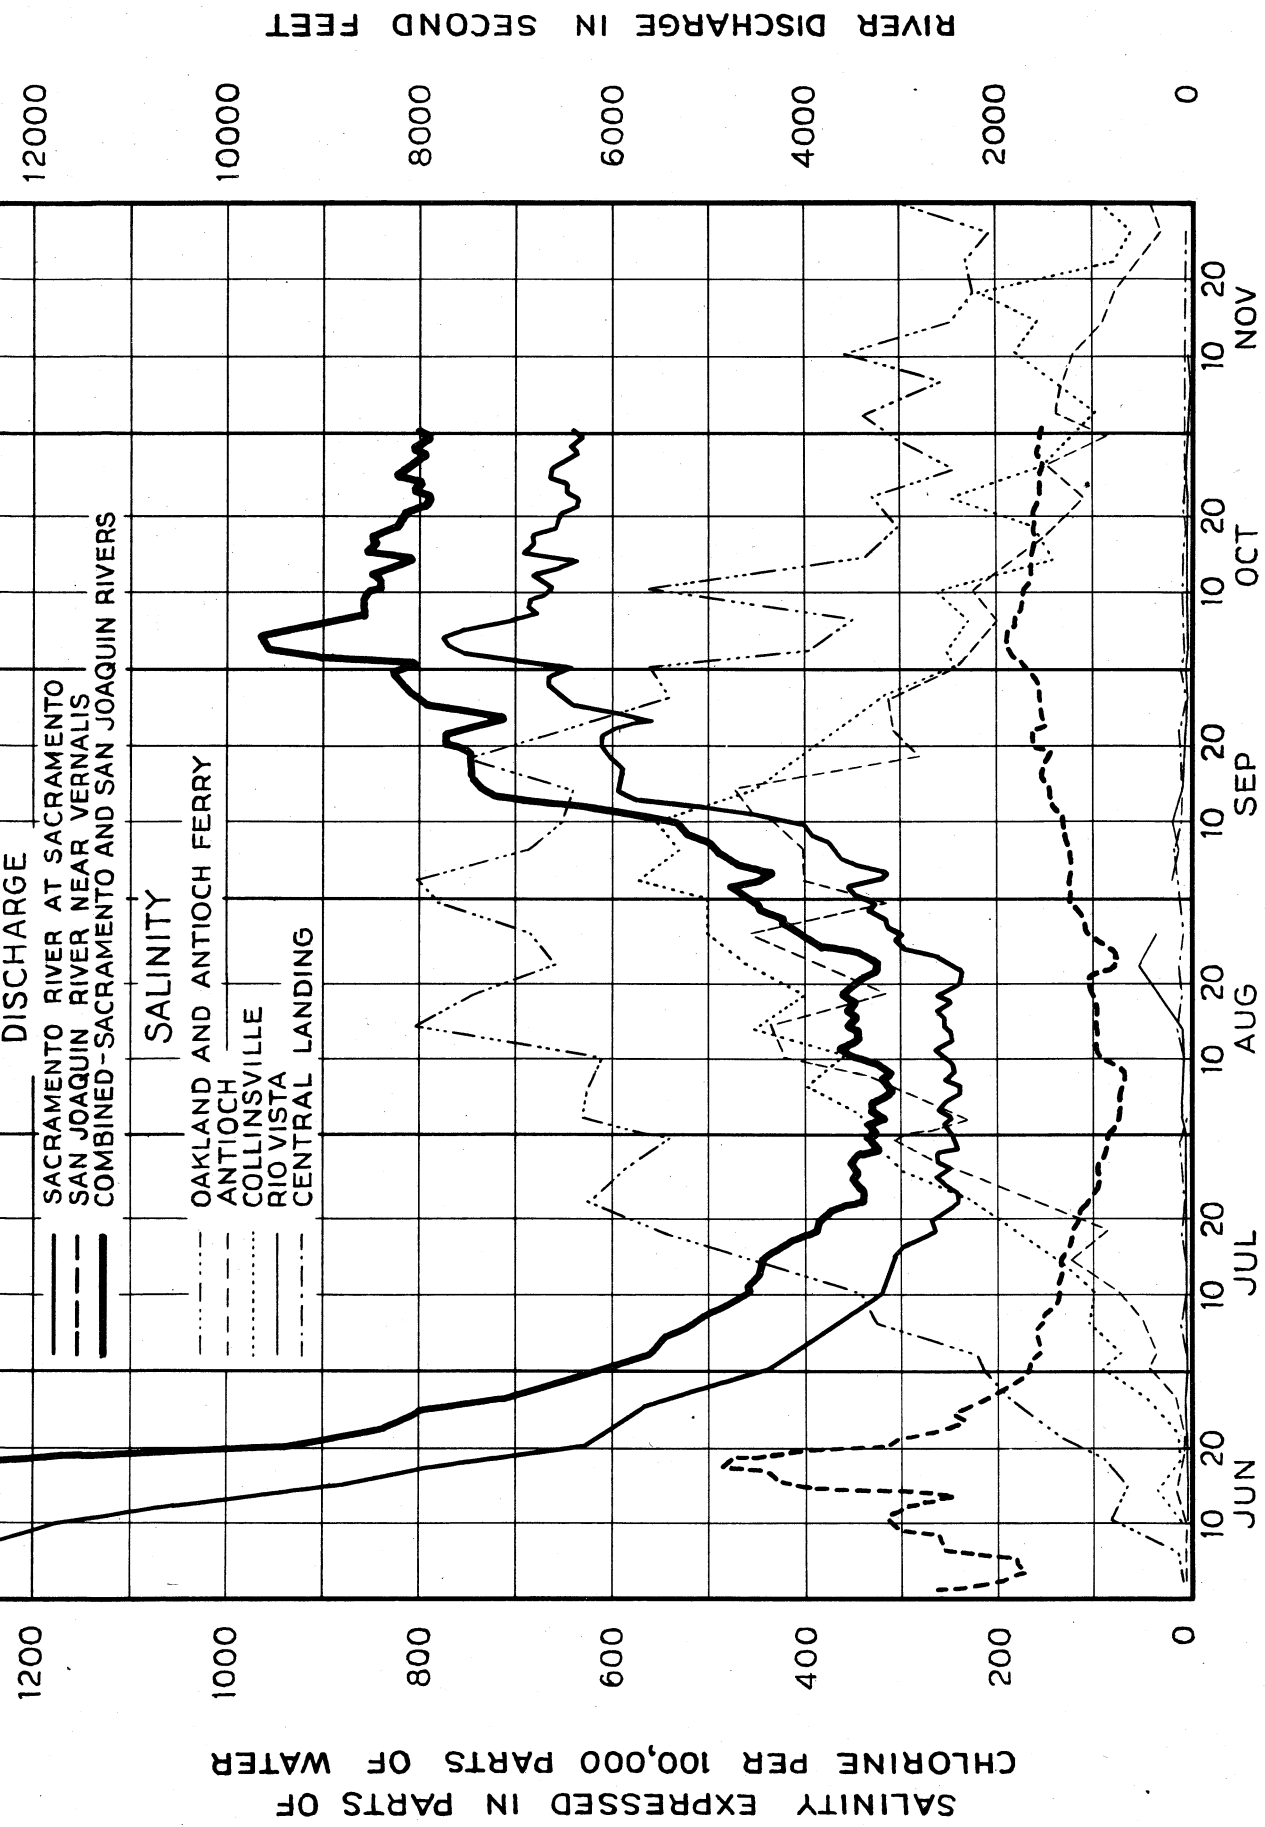

As outlined in previous reports the purpose of these investigations has been to establish as clearly as possible the relation which exists between the discharge of fresh water to the Delta through the rivers, the advance and retreat of the salinity and tidal action. In years of low stream flow it has also had the additional purpose of supplying information to Delta water users in order that their irrigation operations might be so regulated as to avoid the use of excessively saline water.

The scope of the investigation each season has been such as to insure that samples of water to be tested for salinity would be taken at regular intervals at a sufficient number of stations throughout the Delta and in the upper bay region, that the advance and retreat of the salinity from early Summer to late Fall would be completely recorded. In 1930, from June to November, samples were received from forty-six

stations and this number includes twenty-seven stations at which sampling was conducted continuously throughout the year. Tables 84 and 85 give a description and present the results of all sampling for the 1930 stations.

In 1930 the limit in the Delta area above which salinity in the channels did not reach 100 parts of chlorine per 100,000, passed through the lower portion of Brannan and Twitchell Islands, Webb and Franks Tracts and through the central portions of Bethel and Hotchkiss Tracts. This encroachment followed very closely that of 1929 and 1928, also.

Table 83 shows the maximum recorded salinity at bay and Delta stations for the years 1924 to 1930, inclusive, and Plate 7 gives a comparison for the 1930 season, of the river discharge to the Delta and salinity at certain stations.

\* Normal is 40-year mean (1889-1929) of natural run-off at foothill stations. Previous reports have given run-off in per cent of 50-year mean (1870-1920) as given in Bulletin No. 5, Division of Water Resources.  
 (1) For location and description, see Table 84.

TABLE 84

SALINITY STATIONS AT WHICH OBSERVATIONS WERE TAKEN DURING 1930

Station	Miles: : from : : Golden: : Gate :	Location
		<u>SAN FRANCISCO, SAN PABLO AND SUISUN BAYS</u>
Point Orient	: 12.3 :	Upper end S.F. Bay, east shore, $\frac{1}{2}$ mile south of Pt. San Pablo, Wharf of Standard Oil Company.
Point Davis	: 25.2 :	Upper end San Pablo Bay, south shore, Oleum Wharf of Union Oil Company.
Bullhead Point	: 34.0 :	Lower end Suisun Bay, south shore, Wharf of Mountain Copper Company.
Bay Point	: 39.9 :	Center Suisun Bay, south shore, Bay Point Wharf of Coos Bay Lumber Company.
O and A Ferry	: 46.5 :	Upper end Suisun Bay between Mallard Station & Chipps Is. on San Francisco-Sacramento RR.
Innisfail Ferry	: 47.3 :	Montezuma Sl., about 1 mile east of junction with Cutoff Slough. Near most northerly point of Grizzly Island.
		<u>NORTH SAN PABLO BAY</u>
Sonoma Creek Bridge	: 26.4 :	Drawbridge, Sonoma Creek Entrance.
Grand View	: 27.0 :	Petaluma Creek, State Highway Drawbridge, near town of Grand View.
Vallejo	: 29.1 :	Sears Point Toll Bridge, on Napa River, about one mile from Mare Island Navy Yard Causeway
McGill	: 30.6 :	Sonoma Creek at McGill on Northwestern Pacific Railroad, about 1 mile south of Wingo.
Merazo	: 32.7 :	Hudeman Slough Bridge, due south of Merazo station on Santa Rosa branch of Southern Pacific RR.
Lakeville	: 33.8 :	Petaluma Creek, at town of Lakeville, about $7\frac{1}{2}$ miles from mouth of Creek.
Cuttings Wharf	: 36.7 :	Right bank of Napa River, opposite North end of Bull Island, near Carneros Station on Southern Pacific RR.
Napa	: 43.7 :	Bridge on Napa River near center of town of Napa.
Petaluma	: 45.7 :	Petaluma Creek, at Washington Street Bridge in Petaluma.

TABLE 84 (CONTINUED)

SALINITY STATIONS AT WHICH OBSERVATIONS WERE TAKEN DURING 1930

Station	Miles: : from : : Golden: : Gate :	Location
<u>SACRAMENTO RIVER DELTA</u>		
Collinsville	: 50.8 :	North Bank Sacramento River at junction with San Joaquin River.
Emmaton	: 57.7 :	South Bank Sacramento River just above Baker Point Cut, on Horseshoe Bend.
Three Mile Slough Br.	: 60.0 :	At junction of Slough and Sacramento River.
Rio Vista Bridge	: 63.5 :	Right bank Sacramento River two miles below junction of Cache and Steamboat Sloughs.
Junction Point	: 65.2 :	Sacramento River, right bank, just below Steamboat Slough junction.
Liberty Ferry	: 67.6 :	On Cache Slough at junction with Lindsay Slough.
Isleton Bridge	: 68.7 :	Left Bank Sacramento River three miles above junction with Steamboat Slough.
Walnut Grove	: 77.4 :	Left Bank Sacramento River at Upper end of Georgiana Slough.
Sacramento	: 103.5 :	Sacramento River, east bank, at Southern Pacific Railroad Bridge.
<u>MOKELUMNE RIVER DELTA</u>		
Southwest Point	: 78.8 :	Staten Island, north fork Mokelumne River, south bank, just above junction with South Fork:
Camp 33	: 80.2 :	Staten Island, south fork Mokelumne River, north bank, two miles above north fork junction
Tyler Island Ferry	: 81.9 :	On Georgiana Slough, one and one-half miles east of Isleton.
New Hope Bridge	: 87.0 :	North end Staten Island at division point for north and south forks Mokelumne River.
<u>SAN JOAQUIN RIVER DELTA</u>		
Antioch	: 54.9 :	San Joaquin River, left bank, three and one-half miles above Sacramento River junction.
Jersey	: 61.4 :	San Joaquin River, left bank, one mile below mouth of False River.
Twitchell Island Pump	: 65.4 :	San Joaquin River, Twitchell Island, south side, about midway between Seven Mile and Three Mile Sloughs.
Webb Pump	: 72.0 :	Washington Slough, two miles below Old River junction.
Central Landing	: 72.0 :	Bouldin Island, Mokelumne River, left bank, one-half mile above San Joaquin R. junction.

TABLE 84 (CONTINUED)

SALINITY STATIONS AT WHICH OBSERVATIONS WERE TAKEN DURING 1930

Stations	Miles: : from : : Golden: : Gate :	Location
		<u>SAN JOAQUIN RIVER DELTA (CONTINUED)</u>
Ward Landing	: 79.6 :	San Joaquin River. Near Southwest corner of Empire Tract. Near junction of river and Little Connection Slough.
Holland Pump	: 80.6 :	Rock Slough, north bank, one and one-half miles west of Old River junction.
McDonald Pump	: 82.7 :	San Joaquin River, Northeast corner of McDonald Island about 1½ miles below Hog Island.
Mandeville Pump	: 83.0 :	South end Mandeville Island, Connection Slough, north bank, one mile west of Middle River.
Rindge Pump	: 86.1 :	San Joaquin River, north bank, one mile below Fourteen Mile Slough junction.
Orwood Bridge	: 86.3 :	Old River at Santa Fe Railroad crossing.
East Contra Costa I.D.	: 86.7 :	At East Contra Costa Irrigation District pumping plant at head of Indian Slough.
Middle River P.O.	: 87.7 :	Middle River, east bank, at Santa Fe Railroad crossing.
Mansion House	: 88.4 :	Victoria Island, Old River, east bank, at junction with North Victoria Canal.
Stockton Country Club	: 90.8 :	On Lindsay Cut-off (San Joaquin River) north bank, about three quarters mile above Burns Cut-off junction.
Drexler Bridge	: 92.3 :	Middle River, southwest corner of Drexler Tract about one-half mile north of Victoria Canal.
Stockton	: 94.8 :	Near head of Stockton Channel at wharf of California Transportation Company.
Mossdale Bridge	: 108.5 :	San Joaquin River at Lincoln Highway Crossing, about three miles southwest of Lathrop.
		<u>DRAINAGE WATER STATIONS</u>
Jersey Drain	: 61.4 :	Jersey Island, Drainage Pump on San Joaquin River, about 1 mile below False River.
Grand Island Drain	: 68.2 :	Grand Island, Drainage Pump on Steamboat Slough, about 3 miles from Junction Point.
Camp 35 Drain	: 78.7 :	Staten Island, Drainage Pump on South Fork Mokelumne River, 1 mile from junction with North Fork Mokelumne River.
McDonald Drain	: 82.7 :	McDonald Island, Drainage Pump on San Joaquin River, about 1½ miles below Hog Island.
Bacon Island Drain	: 82.9 :	Bacon Island, Drainage Pump on Old River, near junction with Rock Slough.
Mandeville Drain	: 83.0 :	Mandeville Island, Drainage Pump on Connection Slough, about 1 mile from Middle River.
Camp 11 Drain	: 83.1 :	Staten Island, Drainage Pump on North Fork Mokelumne River, 4 miles from junction with South Fork Mokelumne River.
