ACKNOWLEDGMENT

The Division of Water Resources received the assistance and cooperation from many agencies and individuals who have contributed data for this report. The source of the data published herein is noted at the bottom of each page. Particular acknowledgment is made to the following:

Los Angeles County Flood Control District
Orange County Flood Control District
San Bernardino County Flood Control District
Riverside County Flood Control & Water Conservation District
Los Angeles Department of Water & Power
City of San Bernardino
City of San Diego
San Bernardino Valley Water Conservation District
Metropolitan Water District of Southern California
United States Geological Survey
United States Weather Bureau

Without the cooperation of these agencies this report would not be possible, and the Division of Water Resources acknowledges this assistance with thanks.

FOREWORD

The South Coastal Basin Investigation is concerned with the problems of water supply in the southern coastal region of California. As part of this investigation, Bulletin No. 39 was published in 1932 containing "Records of Ground WaterLevels at Wells". Since 1932, water levels at selected wells have been published annually in Bulletins Nos. 39-A through 39-P.

This report, Bulletin No. 39-Q, is the 18th consecutive annual publication and contains water levels for the year 1948.

Locations and descriptions of wells were published in Bulletin No. 39 and are shown on Maps 1 through 8, accompanying that bulletin.

The locations and descriptions of wells in the San Jacinto Valley and Antelope Valley were first published in Bulletin No. 39-J.

They were described by reference to nearby streets and by township, range and section and are shown on maps 9 through 11 included in that bulletin.

A decision was made to publish, in addition to records of ground water levels, seasonal precipitation data within the area. The first such publication of these records was in Bulletin No. 39-A and has continued to be a part of the Bulletin No. 39 series. These precipitation records, supplemented by monthly records of a few key United States Weather Bureau stations, illustrate the distribution of rainfall upon the area. A map showing the location of precipitation stations for which records are published was included

The state of the s

in Bulletin No. 39-A.

A brief discussion of water conditions in the southern portion of the State in 1948 has been incorporated as a part of this bulletin.

CHAPTER I. INTRODUCTION

The coastal area in Southern California, while being one of the most densely populated regions of the State, is an area of deficient water supply. It is because of this disparity that there has been intense activity in water development and water conservation. Besides the development of local supplies, supplemental water has been imported from the Owens and Colorado Rivers and Mono Basin. The intense development of local supplies focussed attention on the importance of compiling basic data appertaining to such supplies and studying the continuing changes in water conditions.

Authorization

The Legislature, by Chapter 832, Statutes of 1929, requested an investigation of plans for the conservation and development of the water resources of California. One of the reports prepared by the Division of Water Resources under Chapter 832, Statutes of 1929, was Bulletin No. 32 published in 1930. This bulletin, entitled "South Coastal Basin", was a progress report consisting of articles by the technical heads of leading public agencies concerned with water problems. Bulletin No. 32 suggested further hydrologic investigations and studies be made.

In order to further the solution of the water problems in the area, the Division of Water Resources undertook a continuing study which has been referred to as the South Coastal Basin Investigation, and this report is issued in connection with that investigation.

Prior Reports

Numerous bulletins have been published from 1932 to date including data on ground water levels, quality of water, value and cost of water for irrigation, water losses and evaporation data, ground water geology, and evaluation of overdraft on ground water basins. These bulletins are listed as follows:

Bulletin No. 32	South Coastal Basin, A Symposium, 1930
Bulletin No. 33	Rainfall Penetration and Consumptive Use of Water in Santa Ana River Valley and Coastal Plain, 1930
Bulletin No. 39	Records of Ground Water at Wells, 1932
Bulletins Nos. 39A through 39P (1933 to 1947)	Annual Reports of Ground Water Levels at Wells and Precipitation Records
Bulletin No. 40	Quality of Irrigation Waters, 1933
Bulletin No. 40A	Detailed Analysis Showing Quality of Irrigation Waters, 1933
Bulletin No. 43	Value and Cost of Water for Irrigation in Coastal Plain of Southern California, 1933
Bulletin No. 44	Water Losses Under Natural Conditions from Wet Areas in Southern California, 1933
Bulletin No. 45	Geology and Ground Water Storage Capacity of Valley Fill, 1934
Bulletin No. 53	Overdraft on Ground Water Basins, 1947

Scope of Report

This report includes in addition to this introductory chapter, Chapter II, Water Conditions; Chapter III, Records of Ground Water Levels; and Chapter IV, Precipitation Records.

In Chapter II, a brief description is given of precipitation,

runoff, storage in surface reservoirs, importations, quality of water and change in ground water levels.

There follows in Chapter III, records of ground water levels for a total of 1,042 wells in the Los Angeles, San Gabriel, and Santa Ana River basins and in Antelope Valley.

In Chapter IV, is presented monthly records of precipitation for ten United States Weather Bureau stations and annual records of precipitation for 281 stations throughout the area.

Precipitation

The primary source of replenishment of the water basins underlying the South Coastal Area is precipitation on overlying lands and on hills and mountains tributary to them. There is a wide variation in the amount of precipitation upon this area from year to year causing variations in the accretions to the ground water. During the period July, 1947, through June, 1948, precipitation on the Coastal Plain averaged only about 50 per cent of normal based upon the 53-year mean (1883-84 through 1935-36) as shown in Table 1, "Precipitation Indices". The 1947-48 season was the fourth driest period of record and the calendar year 1947 was the driest ever recorded based upon records of the U. S. Weather Bureau Station, at Sixth and Main Streets in Los Angeles.

Mean annual precipitation varies from about 12 inches along the coast to 50 inches near the crest of the mountains. Near Riverside where the Santa Ana Mountains interfere with normal movement of air from the ocean toward the mountains to the north, mean annual precipitation is only 11 inches as compared with 25 inches at about the same elevation in the San Gabriel Valley where there is relatively little interference from the low hills which bound it on the south.

Rainfall intensities were generally light throughout the area with a few scattered storms producing some heavy rainfall of short duration. One such storm occurred in San Pedro on December 5, and produced 0.56 inch in five minutes, 0.74 inch in 10 minutes, and 1.08 inches in one hour.

No major storms occurred during the year.

Runoff

Runoff of precipitation from mountain and hill areas is a major source of replenishment of the ground water supply. As rain falls on these areas it is collected in surface or subsurface streams and reservoirs. A major portion percolates to the underground basins where it remains in storage for future use while the excess flows to the ocean and is wasted. The rate of replenishment of these basins is dependent upon many factors, some of which are: intensity and duration of precipitation, type of soil, and condition of the basin.

A tabulation of runoff in rivers and creeks in the Southern California region for 1947-48 is shown in Table 2 with a comparison of maximum, minimum, and mean runoff for each station.

Storage in Surface Reservoirs

The regulation of underground reservoirs for storage is infeasible in some instances and impossible in others, making it necessary
to resort to surface reservoirs for the storage of a part of the natural
supply that would waste to the ocean. This has been accomplished with
the construction of dams forming such lakes as Lake head on the Colorado
River, Big Bear Lake, Lake Crowley, Lake Henshaw, and others.

The amount of water in storage in these various reservoirs on September 30, 1948 was, in most cases, far less than the available capacity. In Table 3 is shown the amounts in storage in reservoirs in Southern California at the end of the year 1947-48, and the capacity of each.

. . . Importations

Owens Valley and Mono Basin

The major source of supply for the water needs of the City of Los Angeles is from the Owens Valley and Mono Basin located about 200 miles north of the City. This source of additional supply was developed when it became apparent that the flow of the Los Angeles River would no longer meet the demands of an increasing influx of new residents and of intensive industrial expansion. The snow fed creeks of the High Sierras are stored in Grant Lake and Lake Crowley for release through the 238 mile long Los Angeles Aqueduct to supplement the local supply. During the year 1947-48, 306,000 acre-feet of water was imported from this area.

Colorado River

In the early twenties it became apparent that an additional source of supply would need be developed for the semi-arid regions of Southern California. Attention was focused on the Colorado River and in 1923 the City of Los Angeles conducted a preliminary study of the river as a source of supply, followed, in 1925, by preliminary surveys and investigations. The Metropolitan Water District of Southern California was organized in 1928 with 11 member cities, and in 1930 it took over all engineering and other work from the City. Construction began in 1932, and the first delivery of softened water was made to Pasadena in June, 1941. In 1947-48, a total of 64,000 acre-feet of softened and 59,000 acre-feet of unsoftened water was delivered to member cities and districts. The gross diversion into the aqueduct of about 145,000 acre-feet for the fiscal year 1947-48 represents only about 12 percent of the

right of the Metropolitan Water District to water in the Colorado River.

Quality of Water

The Division of Water Resources has, since 1946, conducted an intensive program of sampling and analyzing surface and ground waters in the South Coastal Basin. These samples were analyzed in the laboratory of the University of California, Citrus Experimental Station in Riverside and included the following determinations: (1) specific electrical conductance; (2) hydrogen ion concentration; (3) carbonate and bicarbonate; (4) chloride; (5) sulfate; (6) nitrate; (7) calcium; (8) magnesium; (9) sodium and potassium. A quantitative analysis for boron was also made.

When conditions are such that extractions from a basin bordering the ocean exceed net recharge over a long period of time, the possibility of sea water intrusion exists. The hydraulic gradient is reversed allowing sea water to flow into the basin, causing degradation of the local supply. This phenomenon has existed in the West Basin for a number of years and is becoming increasingly prevalent along the coast south of Long Beach. An increase in the rate of intrusion has taken place in both of these areas during the past several years.

A tabulation of analyses of samples taken at key wells is shown in Table 4. An inspection of these analyses reveals all samples to be of a good chemical quality.

Changes in Ground Water Levels

Four consecutive years of subnormal precipitation, a rapid increase in population, and increased export of sewage to the ocean all combine to deplete the already inadequate supply of water in the South Coastal Area. Following is a brief summary of ground water conditions in subdivisions of the South Coastal Basin, and a table showing changes in elevation of water levels at key wells in these subdivisions.

San Fernando Valley Area

The water table in this area continued to drop for the fourth consecutive year. From the fall of 1947 to the fall of 1948 the drop averaged about four feet.

Coastal Plain Area-Orange County

Ground water levels in the Coastal Plain Area continued to fall at such a rate as to make the intrusion of salt water imminent in the pressure section of the basin. A decided drop in water surface elevation also occurred in the forebay area.

Upper Santa Ana River Valley Area

In this area, as in other areas throughout the southern section of the State, the drought was evidenced by a decline in the water surface elevation. The drop is not as critical in this area, however, as it is in the coastal areas.
