Bulletin No. 69-71, the ninth of an annual series, describes the general weather patterns preceding and during the storm periods of the 1970-71 water year, precipitation characteristics, and the resulting runoff; and presents information on flooded areas. It also includes tabulations of precipitation comparisons and peak streamflows and stages; hydrographs of streamflow and reservoir operations; and weir overflow graphs.

ABSTRACT

The weather pattern for water year 1970-71 was marked by extremes that set several weather records. The year held the wettest November for San Francisco and Stockton, the longest winter drought at Red Bluff, the heaviest 24-hour rainfall in southern California, and the deepest snowpack at Norden in December and January.

The Flood Operations Center was activated on a 24-hour basis from November 28 through December 29, 1970, and again from January 15 to 20, 1971. No major emergencies arose and the Center had to take no special action.

The completion of two new dams this year is expected to ease future flood control operations. Bullards Bar Dam on the North Fork of the Yuba River and New Don Pedro Dam on the Tuolumne River will reduce floods.

A series of storms hit the North Coastal Hydrographic Area from October through December, causing flood stages on some rivers. A winter drought occurred from mid-January to early March. A new series of storms moved in during March. No major high water damage was experienced in the area.

The San Francisco Bay Hydrographic Area was drenched by November storms that dropped almost three inches of rain on San Francisco and more than four inches of rain on Marin County in one two-day period. Heavy local runoff resulted in both areas, with the Napa River near St. Helena rising nine feet in nine hours. No streams exceeded flood stage. The rest of the water year was marked by a midwinter drought, a wet spring, and intense summer temperatures.

The Central Valley Hydrographic Area had light precipitation early in the water year. November and December were very wet months, and large amounts of snow were deposited in the Sierra Nevada in December. The Central Valley had little rain from January to March, when a new series of storms brought heavy rain to the mountains. Both Shasta and Oroville Reservoirs prevented downstream flooding. Low releases kept river stages low.

The water year in the South Coastal Hydrographic Area was preceded by brush and grass fires that denuded vast acreages and created a mudslide hazard. Torrential rains in November and December 1970 did cause mud slides and flooding throughout the area and heavy snows closed a major highway. January was a dry month. In February a severe earthquake centered in San Fernando Valley extensively damaged the Upper and Lower San Fernando Dams; 80,000 valley residents were evacuated until the lower reservoir was drained.

## INTRODUCTION

Flooding in California during the water year October 1, 1970, to October 1, 1971, was minor, although extreme weather patterns prevailed throughout the State. A number of weather records were set, including the wettest November on record in San Francisco and Stockton, and the heaviest rainfall for a 24-hour period in Southern California. Storm durations also set records; Sacramento recorded 15 consecutive days of measurable rain. Early season snow in the mountains was extremely heavy. The snowpack at Norden was the deepest of record for December and January. Conversely, the entire State was subjected to a midwinter drought in February. It was the longest drought of record in Red Bluff.

In mid-October rain fell in the North Coastal regions and the Sacramento Valley. These rains were light and the streams and rivers responded only slightly. Storms during the first of November also had very little effect on the rivers, but on the weekend before Thanksgiving a storm entered California from the northwest through the Smith River Basin, causing minor rises on the North Coastal area rivers. When the storm moved into the Sacramento Valley, rivers rose slightly.

A new storm a few days after Thanksgiving dropped heavy amounts of rain on both the San Francisco and Sacramento areas. High gusty winds knocked down powerlines and trees. A substantial runoff in San Francisco and Daly City flooded streets. Rivers rose rapidly to warning stages in the upper Sacramento Valley, and to floodstages at Bend Bridge, at the town of Tehama, and at Vina Bridge. Further downstream

rivers did not exceed flood stage, although flow did occur in the bypass system.

Storms continued to move into the State throughout December, keeping rivers at moderately high levels. January brought new storms, but no major flooding. February was very dry, but in March another series of storms arrived. These dropped only light rain on the valleys but large amounts fell in the mountains, causing heavy runoff at high elevations. The reservoirs restrained this runoff, forestalling floods in the Central Valley. Precipitation during the rest of the water year dwindled so that, despite the auspicious beginning, precipitation for the year was only normal to below normal.

From November 28 to December 29 and again from January 15 to January 20, the Flood Operations Center in Sacramento operated continuously. However, no major emergencies arose and the Flood Center staff was not required to take any special action.

Before the water year began, the Los Angeles-San Diego area was subjected to some of the worst brush and forest fires the State has ever known. Because the denuded slopes gave promise of massive mud slides and debris flows, the region was declared a disaster area, making emergency flood control funds available to the counties. Money was also allocated to reseed the burned slopes so that new plant life could be started on the slopes before the major rain season. Although late November storms set rainfall records throughout the area, later storms were not as intense or lengthy as had been feared. The denuded slopes

caused no major disaster, although some large mudslides and debris flows did occur.

The increase in flood storage capacity provided by two new dams completed early in the water year is expected to significantly influence flood flows in the Central Valley. Bullards Bar Dam on the North Fork of the Yuba River and

New Don Pedro Dam on the Tuolumne River will greatly reduce flooding on these rivers.

Hydrologic data presented in this bulletin are supplied by several agencies, both public and private, and are considered reliable and accurate. However, these data may be revised on the basis of subsequent information.

### WEATHER PATTERNS OF THE 1970-71 SEASON

The first storms entered California in October but, because the soil was unusually dry, very little runoff occurred. November precipitation was above normal over the entire State -- as much as four times the normal value in many areas.

Two major periods of precipitation occurred in November and December: November 4-12, and November 22-December 9. During both, troughs of low pressure developed in the upper levels near the West Coast with a southwesterly flow over California. With this circulation pattern, a series of weather fronts brought precipitation to most of the State.

The pattern over California was associated with meteorological events in Canada. A blocking high-pressure center located over eastern Canada in October moved to northwest Canada in the first half of November and to the Aleutians later in the month. The effect was to force the jet stream at mid-latitudes to move south, shunting the storm track south as well.

The first weather front moved into the State on November 4. At the same time a large high-pressure area bringing cold air from Canada moved south into the Rocky Mountains. This was the first major outbreak of cold air of the season. Two other Pacific cold fronts moved into California during this

period. Precipitation during the nine-days storm totalled 10 to 12 inches on the north coast and in the upper Sacramento Valley, while the northern Sierra Nevadas received eight to nine inches.

A ridge of high pressure in the eastern Pacific during an intervening period, November 13 to 21, brought a brief rain-free period, except for some light precipitation along the north coast on November 15 and 16.

Between November 22 and December 9, an active trough of low pressure was reestablished over the eastern Pacific and storm systems moving over California were renewed. The blocking high was very well developed in the Aleutians during the last week in November, and the weather fronts moved out of the Gulf of Alaska into the upper level trough entrenched along the 130° W meridian.

The weather front of November 24 had a west-east orientation along the Oregon-California border and, on the following day, when this front had moved into central California, it was replaced by a second front similarly oriented at the Oregon border. Heavy precipitation occurred on November 24-25. Another front -- a cold front with waves -- moved into the North Coast area on November 27 and brought another two days of heavy precipitation. Five days later, on December 4, another front with a

strong surge of moisture brought a concentration of precipitation, which culminated in major rises on North Coastal area streams and the upper Sacramento River.

From November 22 through December 9, precipitation varied from 25 to 35 inches at North Coast stations to 25 inches at upper Sacramento stations. Amounts at specific stations are presented in Table 1.

The November 27 front brought cold air in its wake over the entire State, and snow fell in the mountains from November 28 through December 4. The snow level in northern California dropped to 2,000 feet elevation and in the central Sierra Nevada to about 3,500 feet elevation. The December 4 front became stationary near Sacramento, and the advection of a warmer air mass from the Pacific brought a warming trend in northern and central California. December was wet and cool. Above-normal amounts of rainfall occurred over most of the State, except in the desert areas and southern San Joaquin Valley, and heavy amounts of snow fell in the mountains. Heavy precipitation which fell December 2 to 4 was accompanied by a lower snow level. Two additional wet periods occurred from December 13 to 21 and December 26 to 31.

The broad-scale hemispheric flow pattern on the mean upper level chart for December was marked by relaxation of the blocking in Aleutian area and the establishment of a new blocking regime in the Atlantic. The flow over the Pacific Ocean on the mean chart for December was more zonal, with a band of strong winds near Japan and another over the eastern Pacific at 45° N latitude. The southern branch of the second jet dipped south over San Diego and southern Arizona. The mean zonal pattern varied during the third week of the month, when a low-pressure trough of moderate amplitude lay along the West Coast.

By mid-December several fronts had moved through the State. The strongest of these were the occlusions of December 15 to 16 and December 20 to 21, when many stations recorded 24-hour precipitation of 1 to 2 inches. Overall accumulations for the nine-day period were not heavy, but continued precipitation maintained streamflows at moderate levels.

By December 17, a deep, upper level trough was established near the coast. This trough brought very cold air. During the following days a large quantity of snow fell. The National Weather Service office at Mt. Shasta (elevation 3,544) had 2 inches on the ground at midmonth, 10 inches by the morning of the 18th and 22 inches by the 21st; Blue Canyon (elevation 5,280) had 30 inches of snow on the ground on December 15; 51 inches on December 17, 68 inches on December 22, and 82 inches at the end of the month. The total recorded snowfall at Blue Canyon during December was 121 inches, the second greatest amount of record for that month. Significantly heavy amounts of snow fell on December 19 in the Tehachapi Mountains, where drifts up to 8 feet high stopped traffic on Interstate Highway 5. At the National Weather Service Office at Sandberg in Los Angeles County, snowfall in the four-day period, December 18 to 21, totalled 24.4 inches.

The final December storm series began on December 26 and ended January 2, 1971. These were cold storms that deposited snow at low elevations. On December 29, many stations on the north coast and in the Sacramento drainage basin recorded more than 2 inches of rain in 24 hours.

Figures 5 and 11 illustrate how precipitation for November and December varied from normal on the north coast and in the Sacramento Valley.

The important storm of the season occurred in January. On January 10, a prominent ridge of high pressure formed at longitude 160° W and a closed low-pressure

center formed off the British Columbia coast. On succeeding days, the ridge began to build, with its line rotating clockwise over Alaska. The ridge generated a strong northeast jet stream that extended southwest toward a low-pressure trough over the ocean south of Alaska and strengthened the southwest flow at latitude 30° N. This flow, also a powerful jet stream, headed toward northwest California. The fetch of the warm air mass in this flow extended 3,000 miles to the region north and northwest of the Hawaiian Islands. The weather map for January 15, 1971, is shown in Figure 3.

Precipitation began in the North Coast area on January 9, but the strong flow of moist air did not become well developed until January 15. This flow pattern continued through January 18; on January 19, the flow had weakened markedly and the fetch shortened.

Figure 4 presents a time plot of the pressure gradient between San Francisco and Arcata (related to the onshore low-level wind flow), dewpoint temperature at Arcata (moisture parameter), the mean relative humidity between the surface and 500 millibars (mb) at Medford (moisture in depth), the speed of the 700 and 500 mb wind at Medford, and the hourly precipitation amount at the recording rain gage at Klamath. An isohyetal map of the precipitation totals in the 12-day period, January 9 to 10, is shown on Figure 6. The heaviest precipitation occurred January 15 to 17, with many stream gaging stations peaking either late on the 16th or early on the 17th. The area affected by this storm covered the North Coast drainage area through the Russian River Basin, the upper Sacramento River Basin, and the northern Sierra Nevada through the Feather River Basin.

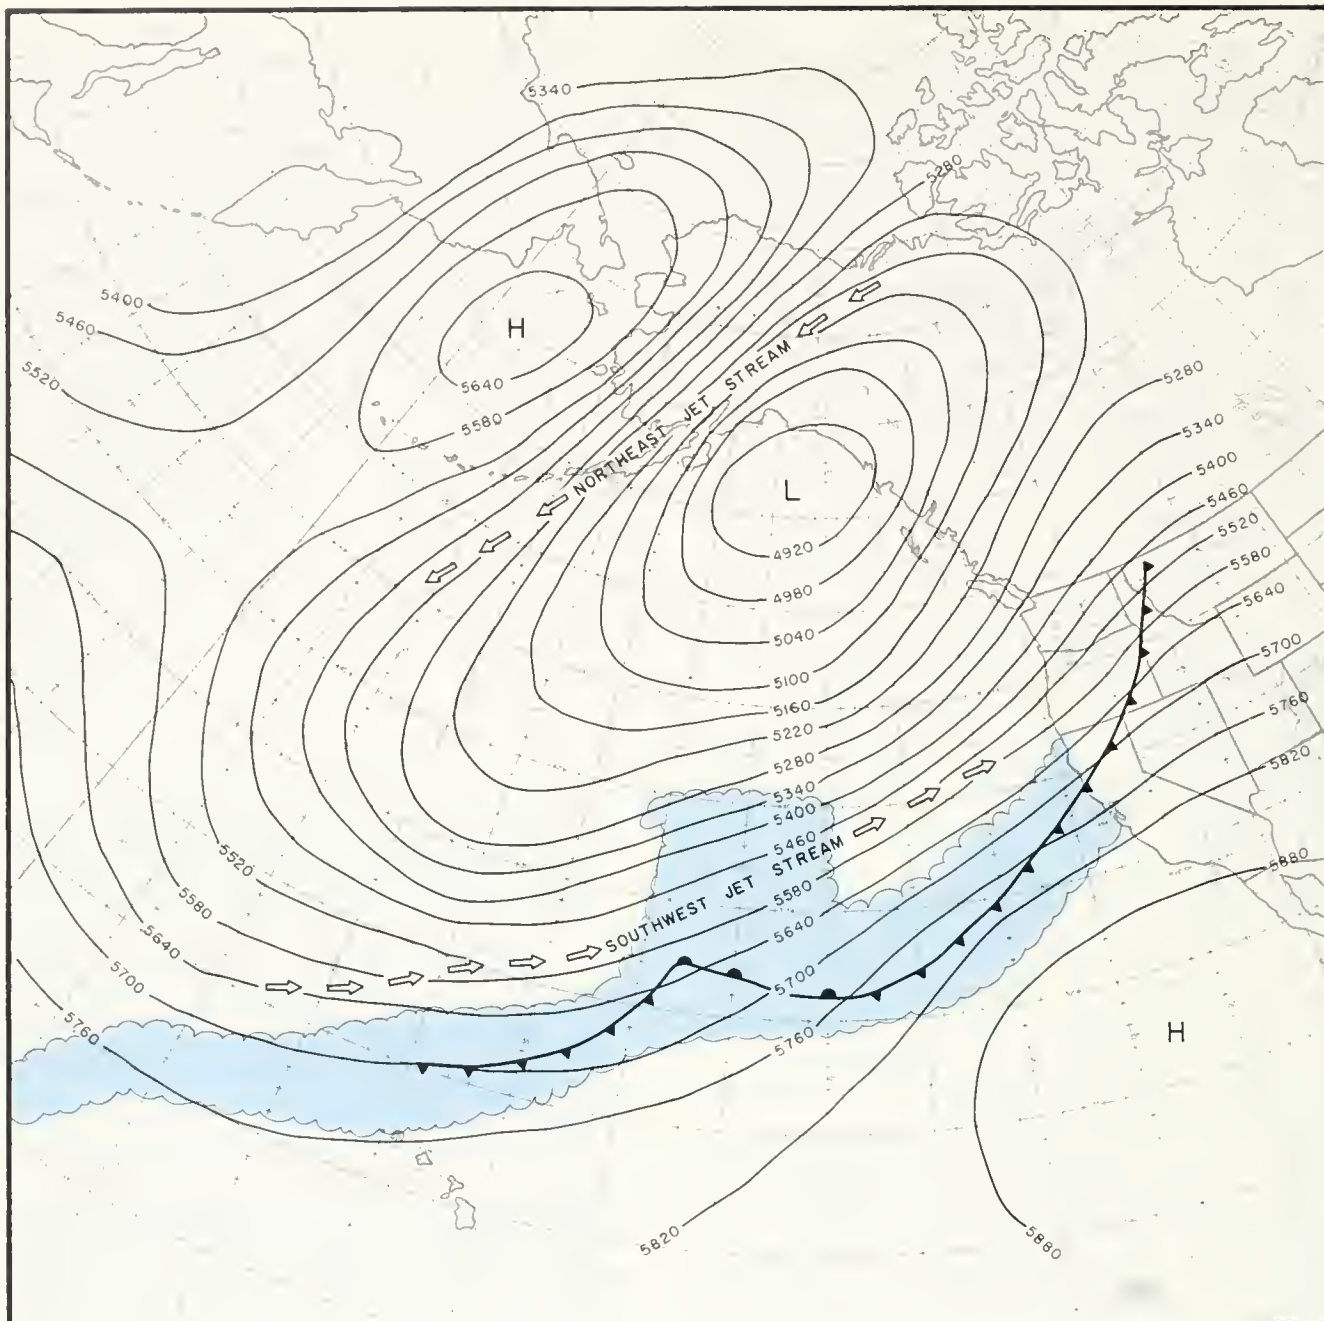

The final significant storm system of the season occurred on March 25-26, 1971. This storm had the characteristics of the classical Norwegian wave

cyclone. A wave formed near the 140° W meridian at 35° W latitude (about 1,200 nautical miles WSW of Eureka), moved towards the Northern California coast, occluded as it approached the coast, and curved northeastwards parallel to the Oregon-Washington coast. Some warm frontal precipitation began falling in the Sacramento Valley on March 25, but the heaviest precipitation came with passage inland of the occluded front. The precipitation amounted to two-day totals of 3 to 5 inches in the north coast and central valley basins; heaviest amounts fell in the Trinity, Eel, and Russian River areas.

## RAINFALL RUNOFF

### North Coastal Hydrographic Area

The North Coastal Hydrographic Area is about 270 miles long and varies in width from about 180 miles in the north to about 30 miles in the south. It is sparsely populated; its prime industries are timber, agriculture, and recreation.

Storms that move into California usually hit this area first before moving into the rest of the State. Storms are also more frequent and intense than in other areas.

Annual rainfall averages are among the highest in the State and range from almost 30 inches in the Russian River Basin to more than 100 inches at some locations in the Smith River Basin. These amounts produce approximately 40 percent of the average annual runoff for the State. Because most of the area is below 8,000 feet elevation, it receives very little snow.

Several major streams and their tributaries drain this area: the Smith, Klamath, Mad, Eel, and the Russian Rivers and Redwood Creek. Smaller streams such as the Ten-mile River, Jug Handle Creek, and Hollow Tree Creek complete the natural drainage.

Throughout the water year, high water caused no major damage. Mud slides which are common to the loosely-compacted soil found in this area brought only nominal damage. Some low-lying agricultural lands received debris and silt deposits. The first storm series in October caused minor rises on the rivers. A new series of

storms in mid-November continued into December, causing rivers to rise rapidly. The Smith and Eel Rivers reached flood stages for a short time. Rivers rose again in January and flood stages were reached again on the Smith and Eel Rivers.

A winter drought began mid-January and ended the first week in March, when rain caused some river rises. Flood stages were recorded at a few locations and some minor flooding was reported.

### Smith River Basin

Smith River, the northernmost stream in the North Coastal Hydrographic Area, drains approximately 720 square miles. About 90 square miles lie in Oregon. The Smith River begins in Oregon, winds through the northwest corner of California, and discharges into the Pacific Ocean a few miles south of the Oregon border.

The basin contains rugged mountains and foothills, most of which are below the 3,000-foot elevation; some mountains along the eastern edge rise to 5,000 feet. This basin is usually the first part of the State to be hit by storms. Rainfall averages nearly 80 inches per year. Some stations receive more than 110 inches per year. Rainfall in excess of one inch per day occurs in this basin about twenty days of every year. Most of this precipitation occurs between October and April, causing high river stages several times a year, and flood stages occasionally.

When the Smith River exceeds flood stage, a phenomenon occurs. Flood water near the mouth of the river flows into Lakes

Earl and Talawa, which lie several miles to the south. These lakes drain into the ocean through a small outlet that must be opened occasionally when a sand bar develops at that point. If this outlet is not opened, lake levels will rise abnormally high and low-lying lands flood. When the lake levels are low, flood water flowing into the lakes from Smith River is confined to several small channels and culverts, and the system acts as a release valve to reduce lowland flooding.

During October, a short series of storms brought light rain to the area. River rises were slight. In November, new storms had much more effect. The Smith River rose to flood stage on November 24 but quickly receded without major damage. During this storm, several rainfall records were exceeded, including that for the 24-hour period at the Gasquet Ranger Station where 6.43 inches fell on November 24.

Heavy rainfall occurred throughout November and much of December. Each burst caused the river to respond but river stages remained below flood levels. Some low-lying roads were closed but damage was minor.

Heavy rain lasting several days began again on January 8, 1971, and caused the Smith River to go slightly over flood stage. Mud and rock slides closed several highways and caused minor damage. During this storm a double peak occurred. The river exceeded flood stage on January 17, then receded. During this rise Lakes Earl and Talawa were low and very minor lowland flooding occurred. The river peaked again 24 hours later at an identical stage but with very different results. Because the lakes were full, the second peak caused extensive lowland flooding, closing highway 199 for several hours.

The remainder of the winter and spring was exceptionally dry. Storms moved through the area, causing some minor

river rises, but all peaks were well below warning stage.

### Klamath River Basin

Lying south and east of the Smith River Basin is the 15,700-square-mile Klamath River Basin, of which nearly a third lies in Oregon. Major tributaries to the Klamath River included in this basin are the Salmon, Scott, Shasta, and Trinity Rivers. It is a rugged mountain area, with elevations ranging from sea level to over 8,000 feet. The basin is sparsely populated by residents employed mostly in logging. It is a prime recreational area.

The Klamath River Basin receives heavy rainfall. Some areas receive as much as 80 inches per year.

During October, storms caused minor rises on the Klamath River and no damage was reported. Another stormy period began in November and caused rapid rises along the river. However, high water was well below warning stage and no damage was reported in November and December. Some low-lying roads were flooded.

Storms with heavy rain and gale winds entered again in January, and this time mud slides closed several roads. One county employee was killed by a slide while working to clear a previous slide. Some lowlands along the river were flooded, but the only damage was deposition of debris and silt. The highest peak of the entire season, which occurred on January 17, was well below warning stage.

Very little additional rain fell in this basin until mid-March when heavy rains hit the basin again, but these only brought minor peaks. No flooding was reported anywhere.

### Eel River Basin

The 3,700-square-mile Eel River Basin is an area famous for its tall redwoods.

Its major tributary is the Van Duzen River. The Basin is made up of rugged mountains having heavily wooded hillsides and elevations ranging from sea level to nearly 7,000 feet. Average annual rainfall ranges from about 40 inches near the coast to more than 80 inches near the headwaters of the Eel and Van Duzen Rivers. Runoff amounts to nearly nine percent of the average runoff for the entire State.

The river carries a quantity of suspended sediment to the ocean that equals 33 million tons of soil per year, the highest average suspended sediment yield per square mile of any river in the United States as large as or larger than the Eel River.

Some light rain fell in the Eel Basin in October, resulting in minor river rises. November storms moved in rapidly, accompanied by gale winds. Runoff caused the Eel and Van Duzen Rivers to rise rapidly, but the peaks did not reach flood stages. These storms continued into December with new rises on the rivers. The upper Eel River failed to reach dangerous stages, but the Van Duzen River flooded its banks at Bridgeville and inundated lowlands for a short time early in December. The lower Eel River flooded its banks near its mouth at Fernbridge at about the same time. Lowlands in the delta were flooded and silt and debris were deposited on low-lying lands.

Numerous mud slides closed several roads but little damage was reported. The railroad was closed for several hours near the town of Pepperwood. The continuing downpour in early December also caused flooding from local runoff in Ferndale and Eureka. Rain showers continued through the rest of December, but no flooding occurred.

After a brief dry spell, rain began again after January 1. The rivers responded quickly and the Van Duzen River peaked slightly above warning stage in the first week of January.

These rises also caused the Eel River to go over flood stage again near Fernbridge. Delta lowlands were flooded and silt and debris deposited. Mud slides closed several highways and local roads. Highway 101, the main north-south route, was closed near Leggett for a short time.

The weather then became unusually dry and remained so into March. In mid-March, storms caused the rivers to rise and flooding was reported along the Eel and Van Duzen Rivers. Flood peaks occurred at several points, flooding lowlands and depositing silt and debris. Flooding along the Eel River during March is unusual. The most recent floods recorded during this month occurred in 1940 and 1949.

#### Russian River Basin

The 1,800-square-mile Russian River Basin, lying at the southern end of the North Coastal Hydrographic Area, contains mountains that rise to nearly 4,700 feet. The Russian River begins in the mountains north of Ukiah and flows south through Healdsburg and turns west and flows toward the ocean at Jenner, covering a distance of nearly 112 miles. The basin is a prime recreational area for people from the San Francisco Bay Area. Numerous summer homes line the river near Guerneville.

October storms produced only minor rainfall in the basin. In November, major storms brought large amounts of rain. Rain early in November had very little effect on the river, but an intense rain squall late in the month caused the Russian River to rise sharply. Continued bursts of heavy rain caused the river to rise to about four feet over flood stage near Guerneville on December 3. Some homes and lowlands were flooded near the river. Two additional wet periods occurred in December and more minor rises took place, but these peaks stayed well below flood stages.

New river rises resulted from January storms. The highest peak approached warning stage near Guerneville and quickly receded. No damage was reported.

This basin was relatively dry from mid-January until the first week of March, when new storms arrived. Dry soil absorbed the runoff and the river only peaked at moderate levels and quickly receded.

#### San Francisco Bay Hydrographic Area

The San Francisco Bay Hydrographic Area extends along the Pacific Ocean from north of Petaluma to near Gilroy in the south and inland to Pittsburg. The area includes land around Suisun, San Pablo, and San Francisco Bays, and several small streams that drain either into the bays or the ocean. Residents of this area must be alert during the winter because these small streams

react quickly to rainstorms. Major streams in the area are the Napa River in the Napa Valley, and Petaluma River, running from near Cotati to San Pablo Bay.

Flooding is chiefly local; flash floods occur on the smaller streams and some floods on the two major streams. Runoff is generated almost entirely by rain since mountain elevations are low and very little snow falls.

Rain showers during October dropped little rain; moderate to heavy amounts were reported in only one short period. Rain began falling again in early November. In the third week of November, a storm front entered the area, stalled over the San Francisco Bay area, and, on November 27 and 28 dropped 2.87 inches of rain at San Francisco. Areas of Marin County received more than 4 inches of rain from this storm. Overloaded storm sewers caused streets to be flooded; the roof of one building

SAN FRANCISCO EXAMINER PHOTO

Heavy downpour on a San Francisco street.

collapsed when its drains could not handle the downpour. Minor flooding was also reported in Alameda, Contra Costa, Marin, and San Mateo Counties. Heavy winds blew trees and powerlines down throughout the area. Water six feet deep was reported at some locations in Daly City and Burlingame south of San Francisco.

Rain continued through December but no further problems occurred. Rainfall was relatively light for the rest of the water year.

### Napa River Basin

The largest stream in the San Francisco Bay Hydrographic Area is the Napa River. It drains the Napa River Valley, a basin about 230 square miles in area upstream of Napa. The river begins on the slopes of Mount St. Helena, flows through the Napa Valley, and discharges into San Pablo Bay near Vallejo.

Storms that passed through the Bay Area in October and early November had little effect on this basin. In late November, a major storm series entered and dropped heavy amounts of rain. Amounts exceeding four inches were reported at several stations in a 24-hour period, with most of the rain occurring in 12 hours. At the St. Helena gaging station, the Napa River rose about one foot per hour for nine hours. However, this peak was slightly below flood stage. On December 3, heavy amounts of rain fell again and the Napa River exceeded flood stage near St. Helena gage. High flow in the Napa River washed out a bridge on Rutherford Road, the only major damage reported.

During the rest of December and early January only light intermittent rain fell, causing some minor fluctuations on the river. All stages remained below danger levels. Storms after mid-January also had little effect on the river. February and the first week of March were extremely dry. In mid-March large amounts of rain fell on the basin. but peaks were well below the danger stage.

High water damage in the basin was light, but other types of weather caused damage. In the early spring, a severe frost threatened crops. Actual losses were nominal and crops responded quickly to warmer weather. During August and early September 1971, the basin was subjected to an intense heat wave, with temperatures ranging near 100° for several days. Vineyards sustained about 30 percent damage.

### Central Valley Hydrographic Area

One of the world's largest and most important agricultural regions, the Central Valley Hydrographic Area consists of all river basins that drain into the Sacramento and San Joaquin Rivers upstream of the point at which the Sacramento River empties into Suisun Bay at Collinsville. The area is about 500 miles long and 120 miles wide, stretching from Goose Lake near the Oregon border to the Tehachapi Mountains, and from the Coast Range to the Sierra Nevada. Annual rainfall is moderate to light, ranging from about 70 inches in the north to less than 10 inches in the Bakersfield area.

Principal streams of the Sacramento River Basin are the McCloud, Pit, Feather, Yuba, Bear, and American Rivers, which flow from the Sierra Nevada, and the Cottonwood, Stony, Cache, and Putah Creeks, flowing from the Coast Range. The Sacramento River runs the length of the Valley from Mount Shasta in the north to the Delta. In the San Joaquin Basin, the San Joaquin River flows north from its origin in the Sierra Nevada above Fresno to the Delta where it joins the Sacramento River near Collinsville. Principal tributaries of the San Joaquin River are the Cosumnes, Mokelumne, Calaveras, Stanislaus, Tuolumne, Merced, Fresno, and Chowchilla Rivers, draining the Sierra Nevada on the east side of the San Joaquin Valley. No major streams flow out of the Coast Range on the west.

Heavy snowfall in the Sierra Nevadas closed schools, blocked roads, and stranded vehicles.

South of the city of Fresno, the Tule, Kings, Kaweah, and Kern Rivers flow from the Sierra Nevada into the Tulare Lake Basin. During high flows on these streams, some flood flows drain from the Kings River into the San Joaquin River by way of the Fresno Slough.

October storms were light and dropped only small amounts of rain in the northern Sacramento Valley. Light rains fell in early November and later that month intense rain began. Heavy rains fell at lower elevations, making rivers rise rapidly, and snow fell at higher levels. Reservoir inflow increased but releases were kept low. The storms continued into December and each new storm caused another rise in river stages. High stages on the Sacramento River caused flows in the bypasses.

These heavy rains ceased in mid-December, ending a record 15 consecutive days of rainfall in Sacramento. Shortly afterward, new storms dumped heavy snows in the upper mountain regions; record snowpacks were noted throughout the Sierra Nevada. By the end of December, a snowpack that represented about 90 percent of an average year's water supply had collected, giving the water year a favorable outlook.

January rainstorms caused new rises on the rivers and the bypasses were flooded again.

After January, the Central Valley experienced a drought until March. A record 50-day dry spell was registered in Red Bluff where only 0.14 inches of rain fell between January 19 and March 10.

Storms in the middle of March deposited heavy rain at higher elevations, while slight rain fell in the valley. Shasta and Oroville Reservoirs protected downstream areas from flooding. Both reservoirs received high inflows, but low releases and light rain kept river stages low.

At the end of September a minor storm front moved into the area, bringing rain to the valley and snow to the mountains. A record 13 inches of snow was reported at Donner Summit from this storm.

### Sacramento River Basin

Beginning at the base of Mount Shasta north of Redding, the Sacramento River flows south through the Sacramento Valley and ends in the Delta below Sacramento. Shasta Lake, above Redding, with a capacity of more than 4,500,000 acre-feet, is the only flood control reservoir on this river. Inflows to the lake from the upper Sacramento, McCloud, and Pit Rivers are released downstream to the Sacramento River. The Sacramento River and its tributaries drain about 26,300 square miles in which annual rainfall varies from about 70 inches in the north to about 15 inches in the Delta.

October and early November storms caused only small rises on the Sacramento River. However, about mid-November a major storm series entered the Valley. On the 27th, a front stalled for the two days along a line extending roughly through Sacramento and San Francisco. The front was accompanied by strong winds, with gusts nearing 45 miles per hour in Sacramento. Extremely heavy precipitation fell throughout the area, causing rapid rises on the Sacramento River and overflow into the Sutter Bypass. The storm also brought record snowpacks to the Sierra Nevada. Rivers rose sharply again when a new storm series arrived on December 4. Flood stages were exceeded at several points in the northern end of the valley, and the town of Tehama was flooded. Continuing rain caused excessive runoff and, because of high inflows into Shasta Lake, releases were increased to 36,000 cubic feet per second to vacate the flood storage reservation. This was the largest release recorded at Shasta Dam for the entire water year.

More mountain snowstorms set new records for early season snowpacks. At Norden near Donner Summit on Interstate 80, a 100-inch snowpack was recorded on December 3, and several mountain roads were closed. The storm series ended December 8, having brought the total snowpack for the period to a level two to three times the normal.

Storms began again on December 13, and on December 16 heavy rains and winds caused severe damage throughout the Valley. Powerlines and trees were knocked down and buildings were damaged. Heavy snows reached as low as 1,500 feet and closed roads and schools. New records for snowfall were set again at Norden. By January 1, 1971, the snowpack in the Sierra Nevada had a water content 220 percent of normal for the date. This represented 90 percent of a normal year's total water supply.

Light continuing storms caused minor fluctuations on the already moderately high river. Runoff into reservoirs was low, and smaller releases kept river stages down.

On January 12 a fierce cold storm brought snow near the 2,000-foot level and closed mountain highways. Interstate Highway 80 over Donner Summit was blocked for 40 hours, the longest such closure since 1964. On the heels of this storm, a warm front moved into the Sacramento Valley on January 15, and rain pushed the upper Sacramento River to flood stage again. High inflows entered Shasta Lake on January 16. After peaks had passed downstream, the lake was lowered to its required flood storage reserve. River stages equalled those of the November-December storms and flooded the Sutter and Yolo Bypasses again. Mountain roads were closed by mud slides. High winds caused damage throughout the valley.

The snowpack began melting at lower elevations, and the runoff held stages in the Sacramento River at moderately high levels for a short time, causing

some bank sloughing and endangering homes near the town of Tehama.

During the 50-day period from January 19 to March 10, only 0.38 inches of rain fell in Sacramento -- the driest comparable period since 1877, and only 0.14 inches of rain fell in Red Bluff -- the driest period for this time of year since records began in 1872.

In March, new rains ended this rare winter drought. The storms hit at high elevations; only light rain fell in the valley. Rivers rose slightly while reservoirs controlling the Sacramento River and its tributaries had high inflows. Shasta Lake had the peak inflow of the season, more than 62,000 cfs. Because the rain fell late in the season, however, the lake was allowed to retain this water. After the storms were over, the lake was filled from snowmelt runoff and only 16,000 cfs were released in April. By mid-May the lake was filled to capacity.

A cool spring slowed snowmelt. Some minor local flooding was caused by spring showers and snowmelt. In early June, a late spring snowstorm followed by a brief period of warm temperatures caused an unusual snowmelt flood near Alturas in the upper Pit River Basin. River channel work in Alturas helped pass flood flows through town without damage. High water threatened the sewage treatment ponds, which were protected by a temporary levee. Flooding on the South Fork Pit River near Likely closed Highway 395, disrupting traffic between Alturas and Susanville for several days. Flood waters also backed up on the low-lying farmlands south of Alturas, depositing silt and debris on crops.

Throughout the summer the mountains were subjected to thunderstorms. One such storm caused flash flooding on Willow Creek north of Portola in Plumas County. High water in the creek polluted the city's water supply with mud. Later in the summer, another intense thunderstorm caused flooding in Susanville.

## Feather River Basin

A major tributary of the Sacramento River, the Feather River was at one time a major threat during the high water season. It is now controlled by Oroville Dam. This structure is the highest earthfill dam in the United States and impounds Lake Oroville, which has a designated capacity of 3,538,000 acre-feet. This dam controls the runoff from a 3,600-square-mile basin.

Rainstorms in the Sacramento Valley during the water year had little effect on this basin. The small storms of October and early November only dampened it. In late November, cold storms deposited snow on the upper regions of the basin, slowing runoff into the lake. The storm series continued into December but raised the lake level slowly. The lake was still below flood control reservations when the storms ended, and releases were small.

Storms in late November caused several mud and rock slides. State Highway 70, the major route through the basin, was closed by a large rock slide and by snow at higher elevations.

Mid-January storms caused a little increased runoff into Lake Oroville. At this time, however, the reservoir was close to flood reservation, and releases from the dam were increased to nearly 15,000 cfs for a few days to maintain it at the required level. Mud and rock slides closed Highway 70 again for a time. Releases from Lake Oroville were reduced to 2,000 cfs when the storms passed.

In March, a major storm brought heavy rain to all but the highest elevations where some snow fell. Resulting runoff was high, and Lake Oroville releases were raised to nearly 14,000 cfs to maintain the flood reservation. Rain continued through the rest of the month and inflow to the lake reached more than 56,000 cfs at one time. Releases

were increased again to nearly 25,000 cfs, the highest release of the season.

Because this storm arrived near the end of the winter season, the reservoir was allowed to fill from continuing snowmelt runoff. It filled for the first time, in its history, with a storage of 3,553,300 acre-feet recorded on June 2, 1971.

## South Coastal Hydrographic Area

The South Coastal Hydrographic Area extends along the Pacific Coast from the Tehachapi Mountains to the Mexican border a distance of about 200 miles, and inland about 75 miles. It is comprised of several river basins that drain directly into the ocean. The principal river is the Santa Ana River, which drains about one-fourth of the area. Other major streams are the Santa Clara, Los Angeles, San Gabriel, Santa Margarita, San Luis Rey, San Dieguito, San Diego, and Tia Juana Rivers. Smaller streams are the Ventura, Sweetwater, and Otay Rivers.

This area is the most densely populated region in California. Its terrain is highly vulnerable to land slippage and rain-induced mud slides that damage homes and other structures in many locations.

Before the water year began, the area was subjected to some of the worst brush and grass fires in its history. Natural vegetation on more than 500,000 acres was destroyed, inviting massive mud slides when the winter rains hit. Los Angeles County was declared a disaster area and special legislation enabled the Department of Water Resources to take remedial measures to prevent flood and debris flows from the burned areas. The Department of Conservation and the Department of Fish and Game were empowered to take measures to alleviate the danger of flooding. The Division of Forestry replanted burned areas in the

Figure 14 : HYDROGRAPHS OF FEATHER RIVER

NOTE 1 Curves are derived from operational data  
 2 Discharge figures are in-channel flow only and do not include overland flow

hope that new growth would start before rains began.

Storms began about November 25, 1970. By November 28 the rain became a torrential downpour accompanied by winds with gusts up to 50 miles per hour. Rainfall records were set throughout the area. In a 24-hour period, 4.03 inches of rain fell at the Los Angeles Civic Center, and 7 to 10 inches were recorded at higher elevations in Los Angeles County.

Mud slides, particularly in the burned areas, closed highways and damaged homes. Flooding closed numerous highways. The storm knocked down powerlines, suspending service to about 130,000 subscribers. Three deaths were directly attributable to the storm.

Storms were light until mid-December. On December 19, 1970, rain fell at the lower elevations and snow fell in the surrounding mountains. Heavy snow closed the Golden State Freeway, the only major highway between Los Angeles and Bakersfield, stranding 1,000 people on a 20-mile stretch of road. Two days passed before the road was reopened.

More storms in late December brought rain and snow to the northern end of the area. Mud slides again occurred and roads were

closed, but damage was minor.

January was relatively dry. Los Angeles recorded less than 0.5 inch of rain.

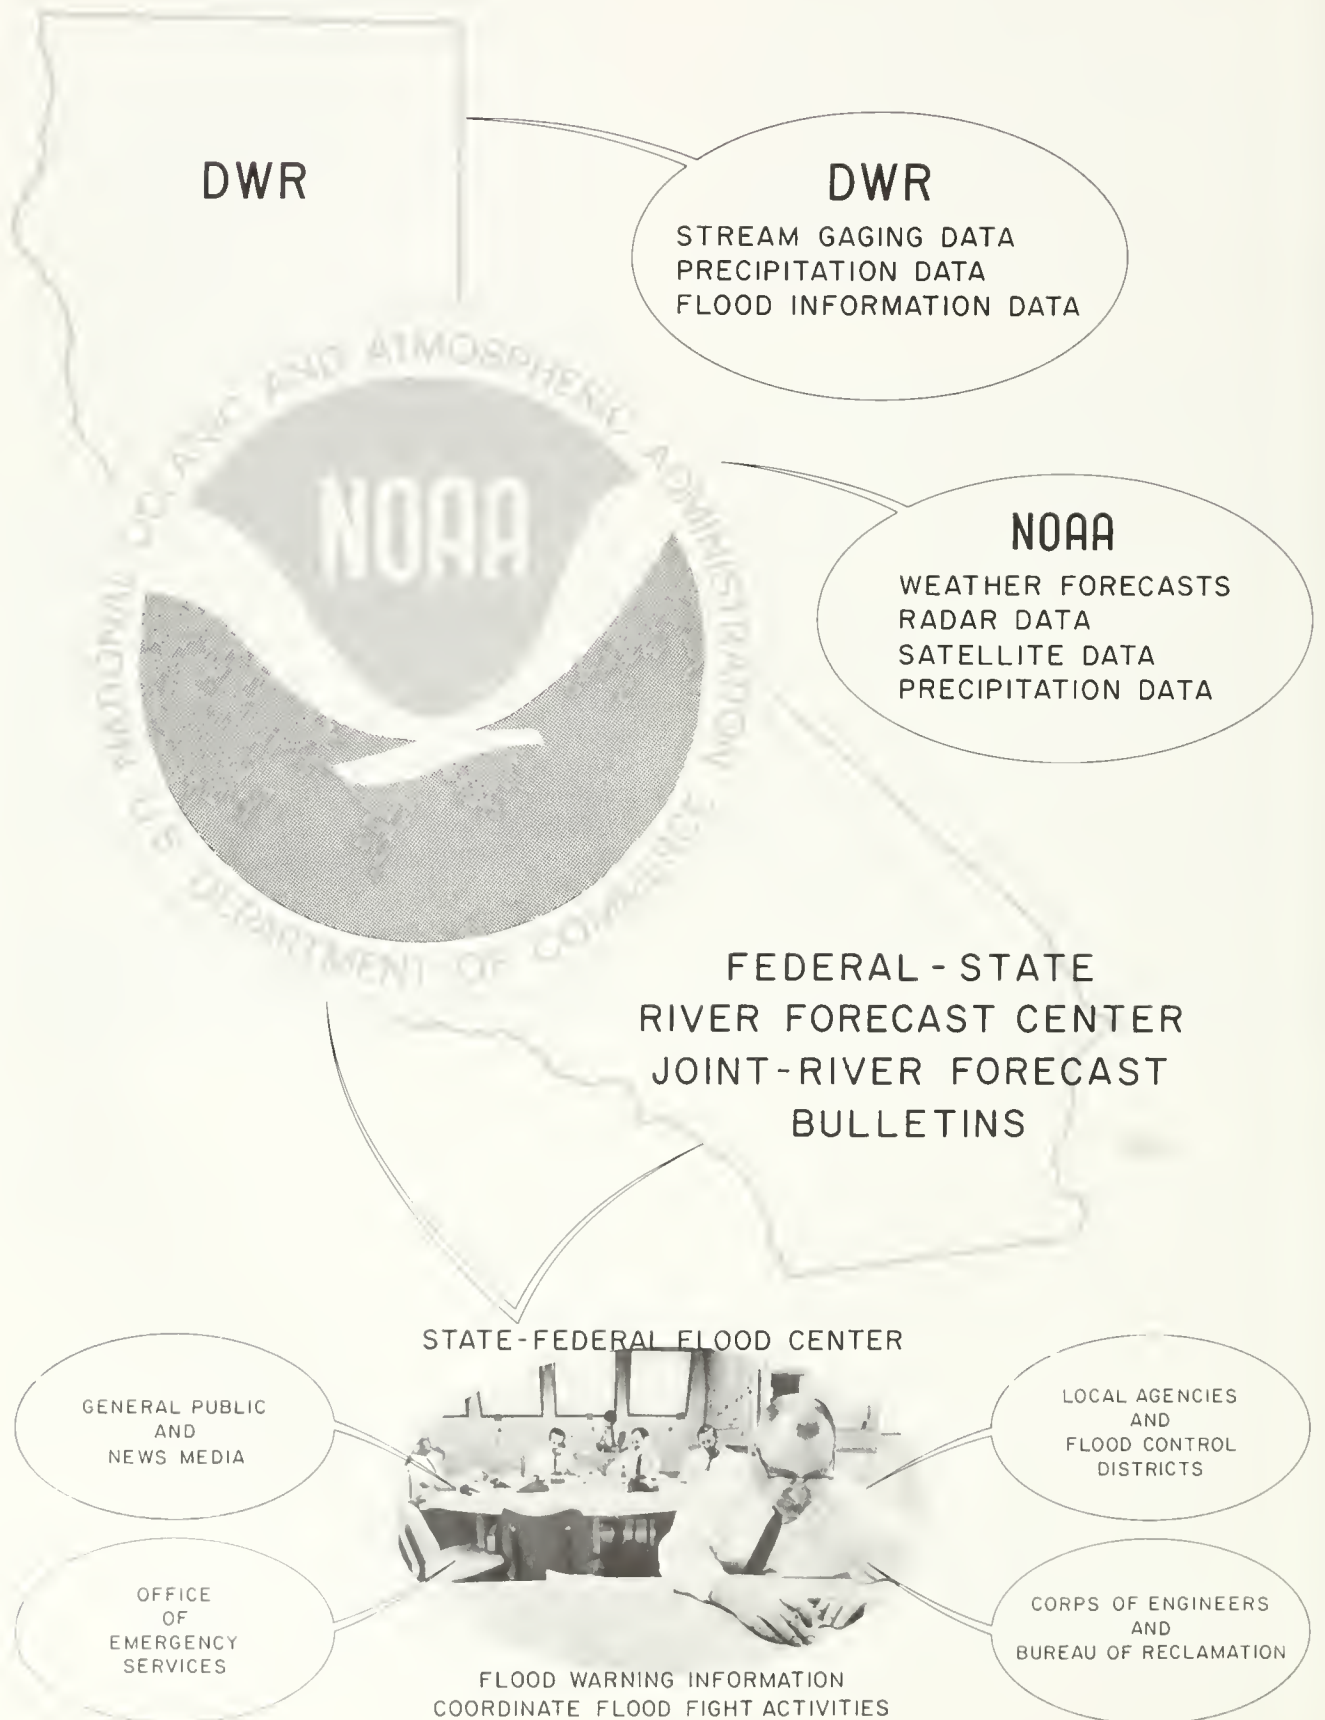

On February 9, 1971, the South Coastal Area experienced a devastating earthquake centered near the San Fernando Valley. Extensive damage occurred as far away as southern Los Angeles. Several major structures, including hospitals, were damaged or destroyed, roads were closed, and 65 lives lost. The earthquake also severed communications and power transmission and interrupted water service and other public facilities.

Three dams in the San Fernando Valley were impaired by the tremors. Pacoima Dam, on the Pacoima River in eastern San Fernando Valley, was damaged slightly, and the two dams in the northern end containing the Van Norman Lakes -- the Upper San Fernando Dam and the Lower San Fernando Dam -- were damaged severely. Damage to the Lower San Fernando Dam was so extensive that 80,000 valley residents were evacuated until the reservoir had been drained.

Storms in the South Coastal Area were light for the remainder of the water year and no flooding occurred. Precipitation and runoff were below normal.

Figure 15

# FEDERAL STATE COOPERATIVE

## STATE-FEDERAL FLOOD OPERATIONS CENTER

Floods in California were uncontrolled until, shortly after the first gold miners arrived in 1849, when levees were built to protect property. As the levees went higher, the river stages also went higher because the flows were constricted to smaller areas; inevitably, the owner with the lowest levee was flooded. In the early 1900s, a coordinated effort was started to solve this common problem. With federal help, levees were built, bypasses constructed, and large dams erected to hold back the flood waters. The work started then has continued to the present and floods have been controlled with increasing success.

However, the disastrous floods of Christmas, 1955, demonstrated the need for a central organization to assemble in one location all pertinent flood information, such as rainfall, river stages, and reservoir operation. The organization would coordinate forecasts of river stages and provide information to all agencies associated with a flood emergency. By the end of 1956, the Federal Government and the State of California had come to agreement and the cooperative Flood Operations Center was established in Sacramento.

Storms during the first half of 1958 tested the Center's capability with six weeks of flooding and flood fighting. The Center functioned extremely well during that first test and has become more efficient through additional experience since that time. The large floods of 1964, 1969 and 1970 have been fought successfully, with the Center providing the nucleus for information, data, and assistance.

The Flood Operations Center consists of the National Weather Service and River Forecast Center as the federal agencies, and the Flood Forecasting and Operations Branch of the Department of Water Resources as the state agency. Its function is to provide all necessary liaison in a developing flood situation.

DWR PHOTO No. 4025-4

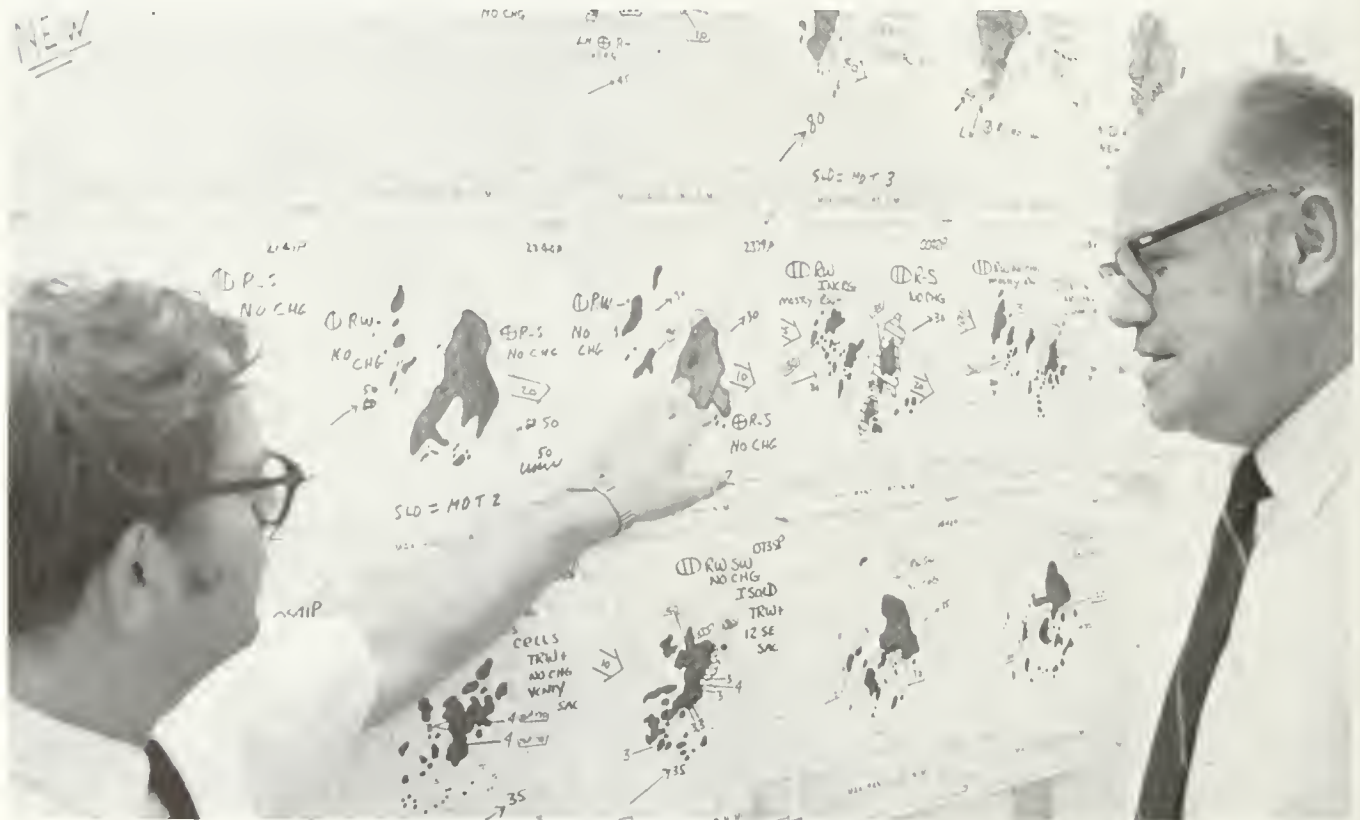

River stage and rain gages throughout the State are interrogated by radio to obtain current storm data. Map shows gage locations.

The Sacramento Weather Office of the National Weather Service, adjoining the Center, is equipped to receive weather data by teletype messages, facsimile weather forecast maps, and satellite pictures. Radar having a 180-mile range is operated continuously during storm periods. This facility plus other radar facilities gives forecasters an up-to-the-minute view of storm location and intensity.

The Flood Operations Center contains a data collection facility that uses several radio and telephone systems to collect real-time data on river stages and rainfall. One radio system monitors the American and Cosumnes River Basins, obtaining data on rainfall, temperature, and water content of the snow; a second system collects rainfall and river stage data in the

Central Valley from Redding to Fresno; and a third system automatically monitors the North Coastal Area from Oregon to Napa, collecting river stage and rainfall data. This North Coast system is also equipped with a readout facility in the Eureka office of the National Weather Service that provides the latest data for local operations and acts as a back-up in case the Flood Center's facility malfunctions. Data is also collected on river stages and rainfall by telephone throughout the State.

Information is obtained from all principal reservoirs in the State on amount of inflow, amount of storage, stage of the reservoir, and present and planned downstream releases. All these data are compiled daily; during periods of flooding or potential flooding, they are collected hourly around the clock.

DWR PHOTO No. 4085-3

Weather and river forecasters review radar overlays depicting a storm situation to check the extent of rainfall.

Reservoir releases are under the jurisdiction of reservoir owners and the Center cannot direct changes. However, the Center is a source of information on river conditions that assist reservoir operators in regulating reservoir operation.

The Flood Operations Center is on alert status from the middle of October to the middle of May. Men from the Center are assigned on a rotating basis to keep continuous watch on the weather and rivers.

DWR PHOTO No. 4085-2

River forecasters assemble storm and river data to forecast expected river stages.

All data collected by the National Weather Service and the Flood Operations Center are used to make a joint forecast of the expected river stages at several points along a river. Forecasts are updated as conditions change until the danger has passed. After the forecast is prepared, it is issued to the responsible agencies and to the public. Forecasts are disseminated by teletype, radio, telephone, television, and newspaper.

As a flood situation develops, the Center is manned 24 hours a day. Members of the Department's levee maintenance inspection team maintain liaison with the reclamation and levee districts. Additional help is provided by specially trained personnel who are

assigned from other offices of the Department of Water Resources. Liaison personnel from the Corps of Engineers and the Bureau of Reclamation move into the Center to keep their offices fully informed. Other Department personnel are dispatched to the flooded areas.

In a flood emergency, all operations are coordinated through the Flood Operations Center. The Center is equipped to communicate by radio with mobile units at the flood sites. All calls for men, material, and equipment are ordered through the Center. When more men are needed on the levees, the Center calls for specially trained inmates of the Division of Forestry Conservation Camps. After the floods have passed, the Center returns to normal routine.

When forecasts are complete, Flood Operations personnel inform other agencies that will be affected by high water.

 (SACRAMENTO RIVER) SHASTA DAM IN OPERATION

**NOTE.**

Data compiled from records of D.W.R. stream gaging station "Sacramento River at Tisdale Weir"  
 Datum: O = O.U.S.E.O  
 Period of record 1935 to present  
 Crest elevation = 45.45 feet

**LEGEND**

- Designates periods of flow over weir
- Designates season of no flow

STATE OF CALIFORNIA  
 THE RESOURCES AGENCY  
 DEPARTMENT OF WATER RESOURCES

**Figure 21**  
**PERIOD OF RECORD OF OVERFLOW OF THE SACRAMENTO WEIR**

**NOTE:**

Data compiled from records of D.W.R. stream gaging station "Sacramento Weir Spill to Yolo Bypass, near Sacramento"  
 Datum: 0 = U.S.E.O.  
 Period of record 1926 to present  
 Crest elevation = 247.5 feet  
 Elevation of top of gates = 310 feet

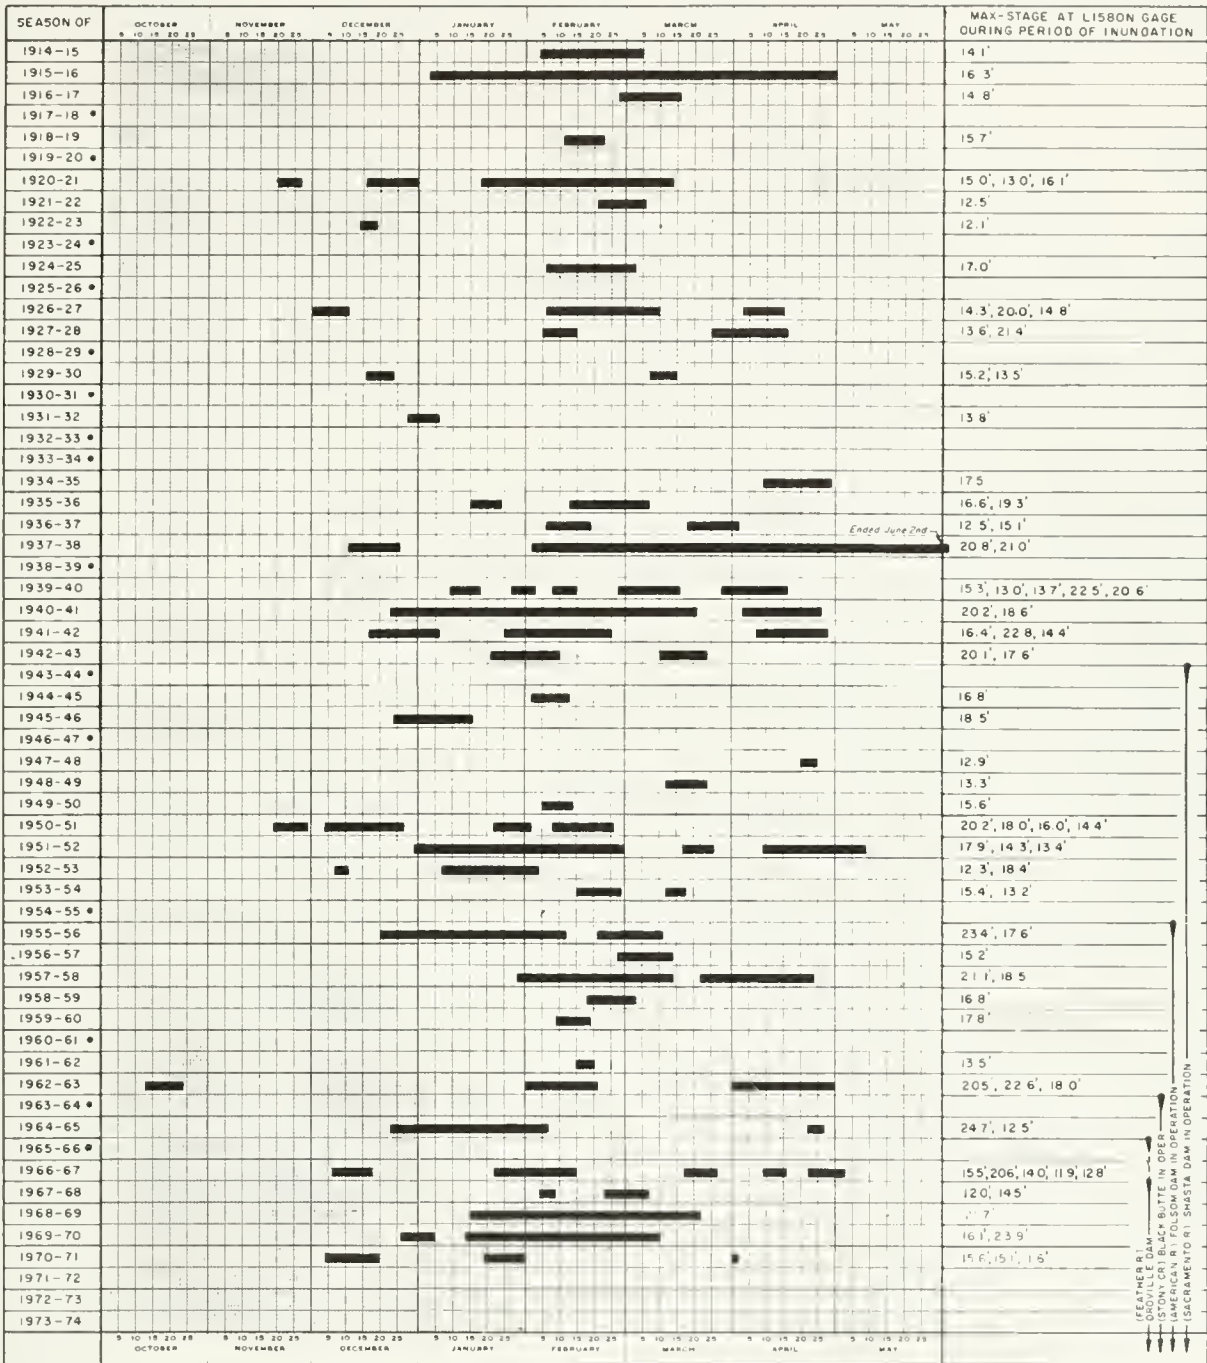

**LEGEND**

- 5 Designates periods of flow over weir and total number of gates opened
- \* Designates season of no flow

**PERIOD OF RECORD OF INUNDATION OF THE YOLO BYPASS**

**NOTE**  
 Data compiled from records of DWR stream gaging station "Yolo Bypass near Lisbon."  
 Datum: O=U S E D Datum  
 Period of Record: 1914 to Present  
 Assumed overflow of Bypass at stage above 11 5' on the Lisbon gage

**LEGEND**  
 Designates period of inundation of Bypass  
 • Designates season Bypass not inundated

## LEGEND

- USGS - UNITED STATES GEOLOGICAL SURVEY.
- USBR - UNITED STATES BUREAU OF RECLAMATION.
- USWB - UNITED STATES WEATHER BUREAU.
- USCE - UNITED STATES CORPS OF ENGINEERS.
- DWR - DEPARTMENT OF WATER RESOURCES.
- PG+E - PACIFIC GAS AND ELECTRIC COMPANY.
- A - FROM FLOOD MARKS.
- B - DISCHARGE OVER WEIR OR SPILLWAY.
- C - SITE OR DATUM THEN IN USE.
- D - DISCHARGE NOT DETERMINED, AFFECTED BY BACKWATER OR TIDE.
- E - ESTIMATED.
- F - FROM DWR TELEMETERING LOG.
- G - PRELIMINARY.
- H - INCLUDES FLOW THROUGH POWER PLANT.
- I - DUE TO FAILURE OF PARTIALLY COMPLETED DAM.
- J - GAGE HEIGHT REVISED.
- K - FLOW THROUGH POWER PLANT NOT INCLUDED.
- L - DISCHARGE AT LATITUDE OF GAGING STATION SITE.
- M - PRIOR TO CONSTRUCTION OF UPSTREAM DAM.
- N - INCLUDES FLOW THROUGH FISH HATCHERY BUT NOT UPSTREAM DIVERSION TO THERMAL TID AFTERBAY.
- P - OBSERVED.
- Q - ESTIMATED PEAK INFLOW TO PARTIALLY COMPLETED OROVILLE RESERVOIR.
- - PEAK OF RECORD.

## NOTE:

THE ABOVE TABLE IS A COMPOSITE OF SELECTED STATIONS THROUGHOUT THE STATE OF CALIFORNIA AND THE DATA THEREIN IS TAKEN FROM USGS SURFACE WATER RECORDS, DWR BULLETIN NUMBER 130, AND UNITED STATES DEPARTMENT OF COMMERCE, WEATHER BUREAU, DAILY RIVER STAGE PUBLICATIONS.
