FOREWORD

The weather patterns of the 1972-73 flood season were characterized by a southerly displacement of the storm track which produced above-normal rainfall through the midcoastal and Central Valley areas of the State. This precipitation produced no significant flooding by any of the State's major streams; however, the combination of abundant and high-intensity rainfall caused local floods and mudslides so large and numerous that ten counties and one city were declared disaster areas during the season.

Bulletin No. 69-73, the 11th in an annual series, covers the period from October 1, 1972 through September 30, 1973. It describes precipitation, runoff, flooding and the general weather patterns that precede and coincide with storm periods. The bulletin also includes tabulations of precipitation comparisons and peak streamflows and stages, hydrographs of streamflow and reservoir operations, and weir overflow graphs.

Information for this bulletin was supplied by the Department of Water Resources, the National Weather Service, the U. S. Army Corps of Engineers, the U. S. Bureau of Reclamation, and many other agencies, both public and private. The assistance of the cooperating agencies is greatly appreciated.

STORMS OF THE 1972-73 SEASON

The winter of 1972-73 was characterized by a west-to-east storm track that was displaced farther south than usual, and that produced seemingly incessant rain, mud slides, and much local flooding from overtaxed storm drains and minor streams. Damages from local flooding, mud slides, and high tides were sufficiently large to cause declarations of disaster areas in ten counties and one city (Figure 1).

With the exception of December, each month of the normally wet period (October through March) produced above-normal rainfall throughout most of the State. In the midsection of the State, it was common for stations to report monthly catchments of from 200 to 400 percent of normal. Although many of the storms produced intense rainfall, the durations were relatively short, allowing the major streams to conduct the runoff without serious flooding.

Because of the more southern track of the storms, the 1972-73 winter was the first season of record in which all of the five major north coastal streams - the Smith, Klamath, Trinity, Eel, and Van Duzen Rivers - failed to reach flood stage. These, usually the first in the State to exceed flood stage, were unusually quiet this season. Only the Russian River, of all the major streams in the State, produced significant flood stages--but no major damage was reported.

On February 11, 1973, a massive mudslide at Haffler Canyon near Big Sur severed State Highway 1, caused the death of a highway equipment operator, and severely damaged a two-story commercial structure. (Photo by the Monterey Peninsula Herald)

October 1972: The pattern of local flooding began in October when an upper level low-pressure center having cold temperatures at its center (a "cold low") formed off the central California coast and persisted for nine days, October 8-17. This stationary low brought a series of storms that passed across most of the State but centered chiefly in the San Francisco Bay and Central Coastal Hydrographic areas. Rainfall totals from the Bay area storms ranged from nearly 3 inches near San Jose to more than 8 inches at Kentfield in Marin County. Half Moon Bay received over 6.5 inches, and San Francisco received 5.4 inches, which was six times greater than the normal amount for the entire month.

In the urban areas of California's mid-section, from the coast to the Central Valley, these storms produced extensive local flooding from swollen streams and overtaxed drains. Street flooding from direct runoff reached such proportions that water surging down a San Francisco street swept a man from a curb to his death.

The major damage areas from these October storms were in South San Francisco and in the Big Sur area in Monterey County. In South San Francisco, Colma Creek went over its banks and flooded much of the low-lying residential, commercial, and industrial sections of the city. In the Big Sur area, these October storms produced the first of a series of damaging mud flows from once-wooded slopes whose vegetative cover had been burned in August. On the basis of this damage, the Governor declared Monterey County a disaster area.

Later in October, Southern California received heavy thunderstorms which produced some flooding in San Bernardino, Riverside, and Los Angeles Counties.

November 1972: The concentration of rainfall through the central part of the State continued in November as the belt of strongest westerlies (jet stream) was displaced south of their usual path. A series of at least nine fronts was carried eastward in the zonal flow over California, bringing heavy amounts of rainfall across the State. Totals for the month ranged from 200 to 400 percent of normal over most of the State, but diminished to slightly less than normal in the extreme northern portions: San Francisco and Sacramento each received over 5 inches of rain (330% normal), San Luis Obispo received 6.8 inches (400% normal), and Big Sur State Park was drenched with 11 inches in three days.

Colma Creek in South San Francisco again overtopped its banks; while mud-laden runoff in the Big Sur area extended the damage begun in October. Mudslides, fallen trees, and flooded homes and roads occurred in many other locations in Northern California; damage was especially heavy in the urban coastal hills. Runoff to the Sacramento River system was sufficient to cause the first overflow of the season to the Sutter Bypass at Tisdale Weir.

December 1972: The southerly storm pattern established in October and continued in November was broken in December when a very deep trough formed over the western states, with a ridge upstream of this trough extending into Alaska. The resulting flow around the Alaskan ridge into the trough brought a strong meridional flow of frigid arctic air masses into the western United States, including California. The State experienced record low temperatures from December 5 through December 16, resulting in heavy agricultural losses throughout California. Cold, fierce storms left snow at such unlikely low elevations as Sacramento, Modesto, and the San Francisco Bay area.

Three to four feet of water on Francisco Boulevard in San Rafael, Marin County, on January 18, 1973. (Photo by the San Rafael Independent Journal)

Total precipitation for the month was generally below normal and no significant flood or slide damage was reported.

January 1973: Weather patterns over the eastern Pacific in January again returned to the prevailing zonal flow of October and November, with the jet stream displaced south of its normal track. During the 14-day period, January 8-21, this flow pattern carried a series of five weather fronts over California. As in October and November, the heaviest precipitation again occurred in the central portion of the State. A strong cold front moved into and through the southern part from January 16-19.

This series of central California storms produced precipitation totals of over 20 inches at some stations in the Russian, Napa, and American River Basins. Cazadero in the Russian River drainage basin reported 22.9 inches of rainfall during the month, with 5.6 inches in 24 hours, and 10.1 inches in 48 hours; Skaggs Springs in the Napa River drainage basin reported 25.4 inches during the month, with 5.5 inches in 24 hours, and a 4-day total of 12 inches; Strawberry in the American River drainage basin reported 27.2 inches during the month, with 5.8 inches in 24 hours and a three-day total of 10.8 inches. Other stations across the center of the State received comparable or slightly lesser amounts of rainfall averaging over 200 percent of normal for the month.

Within a period of eight days (January 11-18), the Russian River exceeded flood stage twice. Each one required evacuation and rescue of residents along the low-lying resort areas in the vicinity of Guerneville. Approximately 70 homes were flooded to some degree and resort shops and businesses suffered losses, but no major damage was reported.

The heavy January rains also produced a multitude of local flooding from overtaxed storm drains and from countless swollen small streams in the Central Valley from Tulare County in the south to Colusa County in the north and along the coast from San Luis Obispo County in the south to Sonoma and Mendocino Counties in the north. Major damage occurred in Marin and San Luis Obispo Counties, and reoccurred in South San Francisco and Big Sur.

In Marin County extensive damage to public and private property was caused by rock and mud slides which destroyed or severely damaged homes, autos, and streets. Flooding from runoff was further aggravated by a series of high tides which coincided with the heavy rains from January 12-17. Damage was estimated at $2 million, and the county was declared a disaster area by the Governor.

In San Luis Obispo County, the cold storm of January 16-19 produced 10 inches of rainfall, with a maximum intensity of 4.5 inches within $1\frac{1}{2}$ hours. San Luis Obispo Creek and Laguna Lake flooded 70 homes in the City of San Luis Obispo, and reportedly swept nearly 100 automobiles down flooded streets. High tides and winds caused damage along the coast; while washed-out roads and swollen streams stranded families and communities inland. Damage was estimated at $7.1 million, and the county was declared a disaster area by the Governor.

In South San Francisco, Colma Creek once again flooded extensive portions of the adjacent residential, commercial, and industrial sections of the City. The combined damages of October, November, and January resulted in its designation by the Governor as a disaster area. Official estimates of flood damage were set at $2.2 million, but claims reached $5.5 million.

Other results of the January storms and high tides included flooding of Edgerly Island in the Napa River delta,

Flood fight operations during flooding of Edgerly Island in the Napa River delta on January 17, 1973. (Photo by the Napa Register)

Van Sickle Island in the Suisun Marsh, and Liberty Island near the downstream end of the Yolo Bypass. When gale winds, high tides, and high river stages combined to threaten protective levees in the Sacramento-San Joaquin Delta, strenuous flood-fighting efforts saved several islands from being inundated.

February 1973: The season's wet regime continued in February. Blocking highs in the Alaska-Siberia sector again held the storm track at a southerly latitude. The major rain-producing storms occurred on February 4-7, 10-14, and 24-28. One-day totals of 2 to 3 inches were common in much of the center of the State and along the south coastal area. The highest intensities occurred in the San Gabriel Mountains north of Los Angeles where stations at Big Tujunga Dam, Mt. Wilson, and Camp Hi-Hill reported 24-hour totals of 7.91, 9.79, and 12.84 inches, respectively, during the storm of February 10-11. For the month of February, these stations reported rainfall totals of 16.38, 22.63, and 25.83 inches, respectively.

Runoff from these storms--on the heels of a very wet January--again produced extensive damage: communities and agricultural areas were flooded from direct runoff and swollen minor streams; roads, bridges, minor levees, and channels sustained severe erosion damage. Although no major river was reported to have caused serious damage, "local" flooding, slides, and erosion was so extensive that, combined with the January damage, seven counties were declared disaster areas. These were Colusa, Glenn, Placer, Sutter and Yuba Counties in the Sacramento Valley, Napa County in the San Francisco Bay Hydrographic Area, and Ventura County in the South Coastal Hydrographic Area. Three counties and a city had previously been declared disaster areas (Monterey County in October 1972, Marin and San Luis Obispo Counties in January 1973, and the City of South San Francisco in January 1973), bringing the total count of disaster areas for the season to eleven--all this without a major flood by a major stream in the State.

But even this impressive number of declared disaster areas does not fully tell the story of local flooding that occurred during February. As examples: 15 San Joaquin Valley families were driven from their homes by flooded Lewis Creek near Porterville in Tulare County; Sacramento Valley communities in Yolo and Solano Counties, which were fields of snow in December 1972, became seas of flood water in February 1973; the storm of February 28 dumped over one-half inch of rain in 10 minutes on the City of Sacramento and flooded streets and underpasses during the evening rush hour; and public and private property in Alameda, San Mateo, and southern Sonoma Counties sustained extensive flood and slide damage.

March - September 1973: The cool, wet weather regime over the State extended through most of March. Eleven weather fronts brought significant precipitation during three periods: March 1-12, 17-22, and 30-31. Although the precipitation was generally above normal throughout the State, the storms were less intense than those of January and February, and no serious flooding was reported. Although the remainder of the season (April - September) produced less than normal rainfall, by the end of March the Central Valley and most of the coastal areas of the State had received over 150 percent of normal annual rainfall and nearly double the amount normal for that portion of the season (October 1 - March 30), despite a relatively cold, dry December.

The Sacramento River was at high stage almost constantly from mid-November 1972 through mid-March 1973. Flood stage was reached at Vina-Woodson Bridge on January 16, 1973, but no damage was reported; the first overflow to the bypass system occurred November 14, and the last overflow of the season did not end until March 15.

Above, Devil's Gate Reservoir filled and sent water over the spillway of the dam to Arroyo Seco. On February 11, 1973, the rushing water reclaimed the natural channel that had been occupied by the Foothill.Freeway bridge falsework. (Photo by the Montrose Ledger)

Left, flooded freeway underpass in Sacramento on February 28, 1973. (Photo by the Sacramento Union)

Some significant erosion occurred along the Sacramento River: two areas required emergency repair by the U. S. Army Corps of Engineers; and some riverbank homes near Hamilton City were threatened but no major damage was reported. With the aid of the major flood control reservoirs, the large streams of the State conducted the runoff from this wet season without major flooding.

Peak Flows and Stages
at
Selected Streams and Stations in California

INTRODUCTION

Appendix B presents data for selected stations on representative streams of the major hydrographic areas of California (Figure 1). The data are obtained from USGS Surface Water Records, Department of Water Resources Bulletin No. 130, and U. S. Department of Commerce, NOAA, National Weather Service, Daily River Stage publications. Current water year data are preliminary and are subject to revision.

Stations are listed in a downstream direction along the main stream and tributaries. Stations on tributaries are listed between main stream stations in the order in which the tributaries enter the main stream.
